THE proposals for the new United Nations Educational and Cultural Organisation were first put forward by the Conference of Allied Ministers of Education, which has sat in London since 1941, and in some of its later work was assisted by a delegation from the United Nations. This body was originally concerned with the immediate and essentially short-term task of securing the educational and cultural reconstruction of those parts of Europe and Asia which had suffered cultural distortion or destruction at the hands of the Axis Powers; and in April 1944 it formulated proposals designed to meet these needs. At San Francisco, however, this aim was extended and generalized, and it was proposed that a permanent special agency of the United Nations, devoted to educational and cultural tasks, should be established. The present Conference is engaged on the problems of giving final form to the draft charter of the Organisation put forward by the Allied Education Ministers, and broadly outlining its main aims and functions and of delimiting its field of action; after which it will set up an interim commission to work out details and to prepare the ground for the first full Conference to be held about a year hence.

Another historical point is also relevant. Since the original sponsoring body was a Conference of Education Ministers, the present Conference is one of delegations appointed by the Ministries of Education of the United Nations, convened by the British Ministry of Education, and presided over by the British Education Minister. Further, the emphasis in the original proposals was largely upon education. Some stress was later laid on culture, and the word 'Cultural' was included in the proposed title; but in spite of the fact that the Allied Education Ministers had a sub-committee to deal with scientific questions, science received less consideration, and proposals to include the word 'Scientific' in the title were at first rejected.

The Ministry of Education has now invited comments from a large number of bodies concerned with the educational, cultural and scientific life of Britain, and undoubtedly the replies of the scientific bodies will have ensured that the fullest consideration will be given by the British Delegation, and may we assume by the Conference as a whole, to the claims of science. However, there is no harm in rehearsing here some of the considerations which occur to most men of science who have given thought to this important subject.

In the first place, they consider it essential that the word 'Science' or 'Scientific' should occur in the title of the Organisation—that, in transatlantic phrase, the Conference should put the S in UNESCO. Opposition to this appears to come from two quarters

—from certain educational circles who fear that the educational side of the new Organisation might come to be overshadowed by the scientific side; and from certain scientific quarters who dislike the idea that science is not 'cultural'. However, although of course 'culture' is a term of such loose definition that it may be stretched to include the totality of man's social activities, it *is* customarily used to include the humanities, literature and the arts, and in contradistinction to science. Further, even if culture in a partially restricted sense can be taken to include pure science, it is difficult for most people to envisage applied science and technology as falling within its sphere. Finally, if culture be enlarged to include science, it should, by the same token, include education as well. Thus, on every ground it would appear right to call the new Organisation either simply 'Cultural', or else 'Educational, Scientific and Cultural'.

However, the question of organization is more important than that of nomenclature. Here, too, most men of science are agreed that it is essential that a separate and relatively autonomous division devoted to the sciences and their application should be set up within the Organisation. There would presumably be other equivalent divisions dealing with education and with culture in the sense previously mentioned; in addition, a further division has been suggested in some quarters to deal with the "General Dissemination of Ideas", that is, the international aspects of the press, radio, cinema and the like, and laws concerning freedom of conscience, speech and assembly.

Each division should then have its own assistant director-general, its own secretariat, its own share of the general budget, and its own representation on the Council or other executive body of the entire Organisation. Such a council, with the director-general of the United Nations Educational and Cultural Organisation as its chairman, and again its own share of the secretariat, would consider questions of general policy and the co-ordination of work between the separate divisions; but most of the actual work of the United Nations Educational and Cultural Organisation would be carried out by the separate divisions.

A subsidiary question remains. Should there be two scientific divisions, dealing with the natural and social sciences respectively; or only one, dealing with both? There is a good deal to be said on both sides. But there is one consideration which is perhaps of an over-riding nature. The time appears to be ripe for extending scientific methods into many fields of social and economic life, both in respect to their study and to their practical direction and control, and for associating workers in the natural sciences with social and economic policy (witness the success of the application of scientific method in so-called 'operational research', in the social activity we call 'war'). If this be accepted, then it would seem important to make the attempt to unite the social and natural sciences and their applications within a single division: if this should prove impracticable, it would be easier to split a single division into two than to combine two separate divisions, each with its own outlook and traditions, its own *amour propre*, its own staff, into one.

There will clearly need to be considerable liaison between the separate divisions of the United Nations Educational and Cultural Organisation (a liaison which will presumably need to be co-ordinated from above by the executive board, and to be effected horizontally between the divisions). Thu the scientific division will be deeply concerned abou the place allotted to science at all levels of education and about the methods of scientific teaching, as wel as with the popularization of science by press, radio etc.; and in so far as the cultural division deals wit philosophy and history, it will be concerned abou the application of methodology of science to thes and similar subjects.

In another article Mr. Crowther deals with some o the specific projects which the scientific divisio might undertake. Here let me merely sketch its mai possible functions. In the first place, it should assist stimulate, and co-ordinate the activities of existin international bodies in science—such as the international scientific unions, the international work i locust control, etc. Secondly, where some field i inadequately covered, or not at all, by existing international agencies, it should either promote such a agency or itself initiate and carry out the necessary survey and research. Thirdly, it should assist an promote the speediest possible diffusion of nev scientific knowledge and ideas—by exchange of books periodicals and reports; by promoting rapid publication; by improved facilities for translation, abstracting, and providing reviews; by promoting specia meetings of scientific workers to discuss pure scientifi problems (notably perhaps in rapidly growin 'borderline' fields) and urgent practical application of science; and in other ways. Fourthly, it shoul assist and promote the exchange of scientific personnel at every level—students, especially researc students; teachers, both in schools and universities mature research workers; etc. Fifthly, it shoul promote world science by assisting the growth o science in countries in which it is quantitatively o qualitatively under-developed—by helping in th provision of books and periodicals and apparatus, b travelling scholarships, research studentships an professorships in both directions, and above all b helping scientific workers in these countries to hav speedy access to new scientific methods and result in the rest of the world. The success of the Britis Scientific Mission to China shows what can be don in this field by bilateral action: this would be mult plied many-fold by proper international organization

So much for a United Nations Educational an Cultural Organisation. But it must be emphasize that, however satisfactory the place of science in thi Organisation, there will remain other importan functions for science to perform in the internationa sphere.

Let us recall the general organization proposed f the United Nations. In addition to the Gener Assembly, corresponding to the Assembly of t League of Nations, there are three Councils directin policy at the highest level. The Security Council wi operate in the political and military field, with speci reference to the preservation of peace. The Trusteeship Council will deal with what were called Mandat Territories under the League, and other similar pro lems. And the Economic and Social Advisory Counci as its name implies, will be concerned with all oth fields in which it is hoped to secure international c operation.

In this section of international affairs, a numb of "Specialized Agencies", to quote the Unit Nations Charter, have been or will be set up deal with particular fields. The United Natio Educational and Cultural Organisation is one these; there are also in existence the Internation

Bank and the International Monetary Fund, dealing with long-term and short-term problems respectively in the financial field, and the United Nations Food and Agriculture Organisation; it is proposed to set up a United Nations Health Organisation in the near future; and the International Labour Office has just decided to divest itself formally of its original connexion with the League and to seek to enter into relation with the United Nations Organisation. It is proposed that all the United Nations agencies of this type should be "brought into relationship" with the Social and Economic Advisory Council; and many people hope that it may be possible to do the same with the International Labour Office.

The precise relationship between the special agencies and the Economic and Social Advisory Council remains to be determined. While there is no suggestion that they shall be mere organs of the Council, it seems clear that they must be subordinate in the sense that they will be on a lower hierarchical level of the General United Nations Organisation; further (with the exception of the International Bank and Monetary Fund, which will be self-supporting) they might perhaps with advantage be directly financed by it through a block grant from the general funds of the United Nations*.

With this proposed set-up in mind, it becomes clear that the United Nations Educational and Cultural Organisation, however important and adequate a role is assigned in it to science, cannot cover all the scientific functions which the United Nations Organisation should exert. In the first place, since a United Nations Educational and Cultural Organisation will be in relationship with the Economic and Social Advisory Council, it cannot be expected to play any, or any considerable, part in relation to the Security and Trusteeship Councils. Secondly, since other special organizations operating in relationship with the Economic and Social Advisory Council have scientific aspects, notably the Food and Agriculture Organisation and the Health Organisation, some machinery is required for co-ordinating scientific policy and for allotting scientific functions as between the different special organizations; and this can only be done at the level of the Economic and Social Advisory Council. And thirdly, the Economic and Social Advisory Council, the Security Council, and the Trusteeship Council will themselves undoubtedly require scientific advice on policy.

Thus while scientific work of an *extensive* type, involving either the co-ordination and assistance or the actual promotion of many detailed and concrete schemes, will fall to the share of the United Nations Educational and Cultural Organisation, and special applications of science to that of the Food and Health and the Agricultural Organisations (and perhaps of the International Labour Office also), *intensive* scientific work, involving advice on and guidance of policy, will be required at the higher or Council level.

This, it may be suggested, would best be achieved by the formation of special scientific committees of the three Councils, which would combine advisory with policy-making functions. In order to obtain the services of the highest-ranking men of science, these Committees should not be drawn from the permanent staff of the United Nations, but should meet at intervals of a few months, presumably in relation to the regular meetings of the Economic and Social Advisory Council and the Trusteeship Council; and for the Security Council, which will be in permanent session, at such times as are proved convenient. An amount of preparatory work on scientific subjects might also be required, which could of course be carried out by a few members of the permanent secretariats of the Councils.

As regards the composition of the scientific committees, the case of the Security Council is the simpler, since the scientific problems with which it is or ought to be concerned are less varied. One may suggest that a committee of 10–15 members would suffice. Owing to the technical and often secret nature of the scientific problems involved, the members would presumably have to be drawn from the permanent scientific advisers of the Armed Services of the eleven nations composing the Council, or from independent men of science who had been closely associated with scientific advisory work for their Service Departments.

It may further be suggested, in view of the overwhelming importance of science in various questions with which the Security Council will inevitably be concerned (such as the control of atomic weapons and the regulation or inspection of pure scientific work in atomic physics), that a proportion of the members of its scientific committee who by virtue of their training are able to understand both the immediate and the long-range implications of scientific ideas and applications, should actually sit at the meetings of the Council itself, as observers taking part in its discussions.

In the case of the Economic and Social Advisory Council, the scientific committee will in the first place require to be more numerous, in view of the numbers of fields of science to be covered—say 15–25 members; normally much of its work might perhaps be best carried out by sub-committees. Secondly, it will not be so imperative that its members should be drawn from among the permanent scientific staff of member nations; a considerable proportion at least could more profitably be selected from independent men of science in universities or research institutes. Among the separate subjects on which their advice would be sought would be the place of science in education, the encouragement of scientific research in general, the application of science to health, agriculture, housing, generation of power, population policy, etc.; but their most important function would be to make the Economic and Social Advisory Council aware of the broader implications of scientific advance for social and economic welfare.

The scientific committee of the Trusteeship Council will presumably have to cover fields such as anthropology, tropical agriculture and medicine, soil erosion, etc., and might include 12–20 members.

The assumption of such important roles by science in the international sphere has certain implications for its future role in national affairs. In Britain, the most obvious need would seem to be the strengthening of the Scientific Advisory Committee to the Cabinet, and the provision of a national scientific secretariat in the Cabinet Office. In addition, the internal apparatus of scientific research councils needs to be reviewed, to see whether there are not any gaps to be filled in it; some men of science, for example, consider that the existing Research Councils (including, of course, the Department for Scientific and Industrial Research) might profitably be supplemented by the creation of a Biological Research Council, which, in addition to covering a wide field of research which is not at present adequately covered by the existing Councils, could take over under unified control some of the biological projects now dispersed among the others.

---

* The converse procedure, by which the special organizations would independently financed, by separate grants from separate member nations, was adopted for the special organizations of the League, namely, the Institute of Intellectual Co-operation and the International Labour Office. It is not, however, in principle satisfactory, as it does not guarantee that all member nations will take part in the work the special organizations, there is less guarantee of nations being arrears with special contributions than with a general contribution the United Nations, and it may lead to nations attempting to attach conditions to their contributions.

To return to the international sphere, it is of great importance that men of science should realize the need for 'high-level' representation of science in the United Nations Organisation, in direct relation to the three Councils. This is all the more urgent since not only is such a function of science in no way covered by the United Nations Educational and Cultural Organisation, still less by the other special agencies, but it has not yet been envisaged by the Preparatory Commission of the United Nations Organisation (see the recently published Report of its Executive Committee)—in spite of the fact that the first session of the General Assembly of the United Nations is to meet in London in January.

WORLD CO-OPERATION IN SCIENCE

By J. G. CROWTHER

THE present Conference and proposals for educational, scientific and cultural co-operation have arisen, in the first instance, through the devastation of war. When countries were invaded, millions of men and women retreated before the enemy, and hundreds of thousands came to the United Kingdom. The children and the young needed succour and education, and through this, the Ministers of Education of the occupied countries met to organize assistance. From immediate help for refugees, they passed to plans for assisting the cultural life of their countries after liberation, and then to the promotion of cultural co-operation on a new world scale. There were the three stages of relief, rehabilitation, and the advancement of civilization.

Each of these stages has its special problems. In the educational field, books and elementary teaching equipment are the most important mass need. The urgency of the provision of text-books, pencils, desks, paper, and the other elementary things is extreme. In principle, it does not seem to be a very difficult problem. The great difficulties that arise in practice are shortage of raw materials, labour, machinery and the organization of production. Their solution would be straightforward, if economic conditions were easy.

In the field of rehabilitation concerned with more advanced institutions, the problems are much less clear. How should a restored physics research laboratory be equipped? Should its old equipment be looked for, and put back; or should modern up-to-date equipment be installed? Should the balance of selection of new equipment be the same as the old?

It is evident that rehabilitation of advanced and university laboratories is a complex and highly technical job. A pooling of world information on equipment and a pooling of world opinion on methods c equipping scientific institutions are required.

The Conference of Allied Ministers of Education which gave rise to the present Conference, has alread done a considerable amount of work on the compila tion of inventories of equipment for a wide range c teaching and academic laboratories. The variou inventories for chemical, physical, agricultura medical and engineering laboratories have been compiled by committees of men of science of variou nationalities.

It is possible that their labours contain the gern of the rationalization of scientific equipment. Th new organization should extend this work.

A second needed activity is the survey of the worl needs of scientific equipment. In the process of it work, the Science Commission of the Conference o Allied Ministers of Education had occasion to estimat the value of scientific equipment that existed in nin occupied European countries. They found that it wa of the order of £100,000,000. There is a striking lac of economic data of this kind. No one ever seems t have asked before exactly what the world needs o scientific equipment might be. It is evident tha such data are essential for the planning of the mass production of scientific equipment at low prices. Fo example, steam-engines of various kinds are neede for engineering laboratories. Their price varie greatly according to whether they are needed in lot of five or five hundred. The cost of scientific rehabilitation could be greatly reduced if the worl manufacture of scientific equipment could be to som extent rationalized.

The world Organisation could promote simila action with regard to scientific and engineering text books. For example, a uniform system of units migh be introduced. A common denominator for th decimal and the foot-pound systems would enabl men of science and engineers to refer to books i any language, without the confusion of incommensurable sizes and units.

Another direction in which there is need fo positive innovation is in the types of research fellowship. Something in the nature of 'research visitor should be invented. There is a great need for th provision of small sums to enable research worke to make short visits for periods of a week to thre months, to demonstrate or learn a new technique, c to travel to a laboratory where there is uniqu apparatus, in order to make a special experimen There is very much less resource for this kind c journey than for studentships and fellowships of on year's minimum duration. The promotion of conta between men of science should be much more flexib and varied. The new Organisation should compare wh various countries are doing in this way, make a li of world resources for means for travel, and direct th attention of particularly good systems that exist one country to the notice of others.

There is general agreement that the small scientifi conference of specialists should be encourage Allied to this development is the provision of accom modation for scientific workers and men of learnin travelling about the world. A chain of houses i the leading cities and centres of the world should b developed, so that a man of science going from o country to another can be sure of a comfortabl informed and inexpensive reception everywhere. pooling of the ideas of the nations on this topic mig lead to interesting innovations.

Yet another direction for development is in th encouragement of new contacts between different branches of science. An efficient world Organisation would have unequalled opportunities for bringing together fertile new personalities and ideas, lying outside the old classifications and organizations. The most obvious ground for development is in the region between the natural and the social sciences.

While new subjects should be stimulated and fertilized, similar attention should be paid to new places. Modern means of transport and communication have brought cities hitherto quite isolated from the cultural current of the world within a few hours' journey of the main centres. A few years ago, the acceptance of a scientific post in an institute in a distant country usually meant cultural exile. With a world Organisation to assist in communications, such an outpost may offer more interesting opportunities to the research worker than he may find in the more crowded and conventional places at home.

A world Organisation for educational, scientific and cultural co-operation, conducted with a positive constructive spirit, can perform great and necessary services in the extension of existing international scientific co-operation, and the creation of new activities to meet the needs of the times.

A PERMANENT INTERNATIONAL SCIENTIFIC COMMISSION

By Prof. J. D. BERNAL, F.R.S.

Birkbeck College

It is sincerely to be hoped that the United Nations Conference for the Establishment of an Educational and Cultural Organisation will, as one result of its deliberations, set up some form of international scientific commission. Such a body has long been needed and never more than in the present period of rehabilitation and reconstruction. The experiences of the War have shown, not only in industrial countries but also in the agricultural and other undeveloped regions, that the rational application of scientific knowledge and the initiation and carrying out of research and development in relation to current problems is an absolute necessity for progress. The War has also shown that the gap which has long existed between scientific research and practical results can, with suitable organization, be drastically narrowed. This experience bears with it the responsibility for seeing that methods at least as efficient shall be put into operation with the minimum of delay for the purposes of peace.

One of the main lessons of war science was its transcendence of national boundaries. In most fields of science there was a complete pooling of British Commonwealth and United States of America scientific resources. In some fields of science, notably medical, the pooling also included, within limits of difficulties of communication, the Soviet Union and China. But the actual geographical extent of scientific collaboration was still wider; it ranged over the whole of the fields of operation of allied armies and supply services, that is, over practically all but enemy-occupied territory. The work was planned and co-ordinated in regard to problems and needs rather than to individual and national contributions. The British Commonwealth Scientific Office in Washington was a focus of common scientific planning and information such as has never existed in the world before and one well justified by its results. There could be correlated, for example, work on insecticides such as D.D.T. being applied all the way from New Guinea to West Africa, and this was not the only centre. Men of science attached to the Middle East Supply Centre at Cairo were examining all the related problems of the region—of agriculture, industry and health—from Morocco to Baluchistan. The advantages to be got from scientific collaboration on a regional basis are now proved; but to safeguard them requires a permanent form of organization which only the United Nations can provide.

Another lesson of equal importance was that the distinction between the different sciences tended to disappear in practice in this type of organization. In fact one of the main lessons of the War was that mixed research teams, ranging from mathematicians and physicists to economists and psychologists, were needed to cope with regional problems in their entirety. Even in highly industrialized countries we are beginning to find out that the physical scientists and the technicians cannot get to work effectively unless they can see their problems in a framework which only social scientists can grasp and which only statisticians can convert into figures on which quantitative action can be taken. This was effectively what was done in the building up of "operational research" during the War, and already the techniques of operational research are being applied to the building and export industries in Britain. The need for them on an international scale will be far greater.

The world of science after the War is ripe for great changes. In the United States and Great Britain science has been relatively undamaged and much increased in scope and effective organization. In the Soviet Union, in spite of the almost total devastation of the western areas, science has not only been maintained but has grown. By contrast, in the majority of the occupied countries, science has barely survived destruction and persecution, while both there and in the countries of Asia and Africa there is an increasingly conscious demand for more science. The devastated countries need immediate help, but it will not be sufficient, or, indeed, desirable, simply to return to pre-war conditions. The smaller countries already feel the need for larger units of scientific intercommunication. In a sense, German science provided this before the War, and the filling of the vacuum left by the perversion and destruction of German science is a task which can only be carried out by organized international action. It should be possible to get away from the conception which had grown up before the War, of scientific circles confined to a large extent by the circulation of journals in the same language, towards one of a world scientific commonwealth. This implies, however, a serious effort to recast the whole system of scientific publication and personal communication.

Such a task is eminently one for the new United Nations Organisation. What is a reconstitution of science in some of the European countries is, for many of the backward countries of the world, a first creation of science. The history of the Soviet Republics of Central Asia shows how rapidly science can be built up and how eagerly it is seized on by a population starting from a medieval standard of culture. During the war years we have seen another example in the extraordinary effort to expand and apply science which has been carried out under the most adverse conditions in China. The part that Dr. Joseph Needham's Sino-British Mission has taken in this effort is an extremely good example of both the needs and opportunities for international collaboration. As a result of this experience, Dr. Needham is convinced that similar international collaboration would be just as much needed and appreciated in all relatively undeveloped countries.

The men of science of this and most other industrial countries have been occupied in the last six years largely with the important tasks of war, and have engaged in international collaboration for that purpose. In this they have learned both of the unity of the natural and social sciences and that of all peoples of the world. The problems of peace can start from this experience, but there is no question of applying it in a mechanical way. Much research and discussion must take place before a complete and effective system of united world scientific collaboration can be built up. This is now of particular importance in the light of the Soviet Government's expressed view that the full organization of cultural and scientific activities should await the setting up of the United Nations Economic and Social Council. It is to be hoped that in a few months time this will have occurred and that both the natural and social sciences will find their place in an all-inclusive international organization.

THE PLACE OF SCIENCE AND INTERNATIONAL SCIENTIFIC CO-OPERATION IN POST-WAR WORLD ORGANIZATION

By Dr. JOSEPH NEEDHAM, F.R.S.

MY experience during the past two years in China in organizing and directing scientific and technical co-operation between China and the United Kingdom has led me to devote much thought to post-war international scientific co-operation. The present memorandum, sketched out in Chicago and Washington in March 1945 and completed in Chungking in May 1945, does not necessarily represent the views of any organization, but are my own views.

In the past, in times of peace, men of science themselves organized periodical international congresses for each science ; and for certain branches of science (though not for all) there were successful international unions, or permanent bureaux, able to deal with day-to-day co-operation. These unions were federalized in an International Council of Scientific Unions, which, however, was not as successful as it might have been, due to the lack of an adequate secretariat. The International Council was associated with the League's International Institute of Intellectual Co-operation, but this itself was imperfect.

In war-time all these international agencies have gone into a state of suspended animation. Under the exigencies of war, the United Nations set up in each others' capitals science co-operation offices to deal with the emergency exchange of scientific and technical information bearing on military affairs. Most of these offices, such as the British Commonwealth Scientific Office in Washington ; the United States Scientific Mission in London (under the Office of Scientific Research and Development) ; the French Scientific Missions in London and Montreal, in general much more efficiently run than anything known to international science in peace-time, deal to the extent of some 85 per cent with war science But in one case (the British Scientific Office in Chungking) a condition more similar to what might pertai in peace-time is found. These science co-operatio offices differ from pre-war international scientifi co-operation mainly in that they have adequat funds, secretariat and mechanical aids ; and are no confined to any one science, but have to promot general scientific co-operation between the countrie which they link. They are, therefore, rather a nev departure ; and point the way for the future.

The pre-war international scientific unions wer thus limited as to subject-matter ; the bilateral scienc co-operation offices are limited as to national scope What we need to-day is fundamentally an attemp to combine the methods which science has spontaneously worked out for itself in terms of peace with those which the nations have had to work ou under the stress of war. None of the machinery ough to be scrapped. The problem is to weld it into satisfactory functioning system.

In the future, there are two other types of international scientific intercourse which may grow up One is the further extension into the scientific fiel of the bilateral cultural goodwill organizations (suc as the British Council, Cultural Division of the Stat Department, etc.). The other is the appointment o scientific attachés in the principal embassies, measure which the continuing interchange of information on war science will almost certainly necessitate While there is much to be said for both these methods I feel that these methods are not fitted to play th major part, though they may well play a valuabl minor part, in the international exchange of s basically international an activity as science. Nov is the time to attempt the establishment of an International Science Co-operation Service in which supra-national loyalty would be possible, as it was i the case of the most successful League agencies.

In general, it may be said that there is a universa desire among men of science to see better internationa scientific contacts after the War. The dependence o all modern world civilization on applied science mus find its expression in the sphere of internationa relations. This desire is more strongly expressed however, the further one goes away from the grea scientific and industrial centres of Europe and th United States. The picture of world science look very different when seen from Rumania, Peru, Java Siam or China.

It is often thought that in science everyone know everyone else, and can, therefore, easily get in touc when any problem arises which calls for it. But th is not the case in the greater part of the world. Venezuelan economic entomologist may have problem very similar to that of a Chinese economi entomologist ; but the difficulties of their comin into touch are enormous. A Rumanian organ chemist may need a few grams of a substance onl being produced in India or Canada ; but if he onl knows his own language it will not be so easy to g it. The Australian workers on alunite needed f years the publications of the Chinese Nation Academy on the same subject; but were never ab to get them until an exchange was arranged throug the British Scientific Office in Chungking.

Allied to what may be called this 'peripher principle' of concentrating the help of an Inte national Science Co-operation Service where it most needed, that is, to the scientific men isolat around the periphery of the 'bright zone', is t omplementary principle of not interfering too much within the 'bright zone'. It would obviously be absurd for any international funds to be spent in communicating between people in the United Kingdom and the United States, for example, who are quite well able to communicate with each other. The International Science Co-operation Service should be directed, and indeed limited, to doing those things in international scientific co-operation which are not being done, and cannot be done, by any other channels.

The problem before an International Science Co-operation Service (or, what we are now coming to, a scientific section of a United Nations Educational and Cultural Organisation) is to steer clear of two extremes. The spontaneously arising scientific organizations before the War too often made the mistake of thinking that the battle was won when the organization was once written down on paper, and eminent men of science in different countries had accepted high positions in it. On the other hand, if care is not taken to select the right personnel, the other extreme of undue bureaucratism will kill the organization. The former danger may be avoided if adequate office management is assured, and the latter will not arise if men of science themselves fully participate.

The United Nations Educational and Cultural Organisation

While these discussions about an International Science Co-operation Service had been proceeding in the scientific world, planning had been going on for the establishment of a United Nations Educational and Cultural Organisation. Draft proposals for such an organization have been published by H.M. Stationery Office for the Conference of Allied Ministers of Education, and are being discussed by the United Nations Educational and Cultural Conference at present being held in London.

In my opinion it is desirable that the word 'science' appears in the actual title of the Organisation. This is essential, since the co-operation of men of science throughout the world is necessary. Many of them are not much concerned with teaching, since they may be in governmental or industrial laboratories; and the word 'culture' does not have in all countries the wide connotation that it has in the United States. Men of science in many countries would be likely to feel that an organization entitled only 'educational and cultural' had little to do with them. Hence I suggest that the full title of the Organisation should be United Nations Educational, Scientific and Cultural Organisation. The word 'cultural' could be assumed to take sufficient care of the humanities and the arts.

I am deeply convinced of the importance of the Organisation's name. I feel that from the psychological point of view, the avoidance of prejudice, etc., names matter enormously. The League's International Institute of Intellectual Co-operation was hindered by the lack of a good 'selling' name, and also lack of any arts of modern publicity to put it across to the intellectual world.

'Applied science' as well as 'pure science' should be written in the Organisation's constitution. If this is not done there might conceivably be a tendency later on to confine the work of the United Nations Educational and Cultural Organisation to matters of pure science without any technological aspect or bearings on the life and needs of the peoples. But pure and applied science can never be separated.

The scientific division of the Organisation should be to:

(1) Promote international scientific co-operation in all its aspects.

This general aim covers all the rest. The United Nations Educational and Cultural Organisation would not be restricted to any one group of sciences. It should also be thought of in connexion with the 'periphery principle' already mentioned.

(2) Organize and assist the better exchange of scientific information and research services between men of science and their organizations in the different countries.

While in the future there may be many opportunities for the exchange of confidential technical information between various countries, there is an enormous field of work to be done in seeing that the information actually published by government scientific organizations reaches those who need it both near and far. Moreover, the availability of scientific journals, especially the more specialized ones, throughout the world, is very restricted, and there is great need for an agency which could help isolated scientific workers with microfilmed or double-contact-printed excerpts from the literature.

Then the system of exchanging reprints, universally used among men of science and most valuable in itself, is very incomplete and unsatisfactory. It needs to be supplemented by other means, especially microfilms, double-contact prints, photostats, etc. If there were, under International Science Co-operation Service, some central stockpile where reprints could accumulate, the work of scientific workers throughout the world would be considerably assisted and much time saved.

In the field of research services, great help could be rendered by arranging for the wider use of special apparatus only available at certain places. It will be a long time before every centre has an electron microscope, a cyclotron, equipment for cutting thin rock-sections, or an ultracentrifuge. In all such work, very often the International Science Co-operation Service of the United Nations Educational and Cultural Organisation would only need to put men of science in different countries in touch with each other.

(3) Work out a plan for the restoration of scientific facilities in the liberated countries.

(4) Work out a plan for the provision of German and Japanese reparations in the form of scientific apparatus and research chemicals.

(5) Work out a plan for the utilization of such surplus war material and equipment as would be suitable for use in scientific research, and its transfer to the more scientifically backward countries.

(6) Assist in maintaining contact between government organizations concerned with science, pure and applied, when necessary; and advise governmental and diplomatic personnel on scientific matters, when desired.

It is probable that government organizations concerned with science in the major countries can communicate with each other quite satisfactorily without the good offices of any new international organization. But is this equally the case between the forestry service of a Balkan country, let us say, and the economic entomology bureau of one of the smaller States in South America? The diplomatic representation of the smaller Powers abroad can never be expected to be elaborate enough to handle all such technical inquiries. There is thus a large scope for an International Science Co-operation Service which would know no limitations of language or geography.

Again, if scientific attachés are appointed in the embassies of the larger Powers, competent advisers will be available to the diplomatic staffs. That this is most desirable would be readily admitted by all of them. But the smaller Powers can scarcely be expected to appoint such advisers, owing to lack of sufficient personnel. There is much, therefore, for the International Science Co-operation Service to do in this direction, and its supra-national character would render it all the better qualified to do it.

(7) Assist the free flow of essential research apparatus, chemicals and equipment across national boundaries.

A helping hand might be very useful, especially in the matter of customs duties and procedures. The International Science Co-operation Service could press, for example, for increased facilities for movements of apparatus, at least in the medical sciences. It would also do everything possible to encourage the production of scientific apparatus by local initiative from materials locally available. The Committee on Scientific Equipment of the Conference of Allied Ministers of Education has already emphasized these points.

(8) Assist the free flow of scientific books, periodicals, microfilms, manuscripts for publication, translations, abstracts, etc., across national boundaries, and especially between world regions of widely different linguistic pattern, for example, those of the ideographic and alphabetic languages.

(9) Assist the free flow of men of science coming and going across national boundaries, whether for periods of study or research, or for congresses, conferences and the like.

Here the International Science Co-operation Service would have to work in close contact with the continuation committees of the great international congresses, for example, those of physics, zoology and geology, usually triennial, and the smaller special conferences which have grown up in special subjects, for example, the Annual Conference on Differentiation and Growth. The more complete the return to normal after the War in matters of travel, passports, and the like, the less need there will be for an International Science Co-operation Service of the United Nations Educational and Cultural Organisation to exert any special influence in the direction of assisting the movements of men of science. But even if this return successfully takes place, there will be room for a long time to come for financial and other assistance to competent men of science to travel.

Allied to this is the helping hand which International Science Co-operation Service could give in the preparation of all kinds of scientific expeditions in zoology, astronomy, etc.

Then again, there are particularly interesting parts of the world which are unable themselves to finance the investigation of their natural products. The International Science Co-operation Service could help, either by financing the necessary investigations or by bringing the need to the notice of the existing world financing foundations.

An interesting proposal has been made by Dr. F. W. Went of the organization of temporary research groups in specific topics. Some of the more important investigators of a certain controversial subject would be brought together for a period of some months in one laboratory, during which time each would demonstrate the experiments on which he bases his own conclusions, and also work with the method and materials of some of his opponents. As examples twelve investigators hold fourteen different theorie of bud inhibition, each man concentrating on a different aspect and using a different experimental plant; and there are no less than ten mutually contradictory theories of translocation of carbohydrates in plants. The expenses of such research gatherings, and the arrangements for them, could properly be undertaken by United Nations Educational and Cultural Organisation.

(10) Promote plans of international collaboration in research.

This, of course, overlaps with the last heading. I would require close contact with the internationa scientific unions, which in the case of such sciences as astronomy, geophysics, geodesy and radio physics have been in the past, and no doubt will again be in the future, outstandingly successful. The United Nations Educational and Cultural Organisation would also encourage the setting up of such unions in sciences which have not previously had them It would also encourage the activities of such essential organizations as the International Committee on Zoological Nomenclature.

(11) Support all international activities of the various national academies of science.

This simply emphasizes the desirability of working in close co-operation with such bodies as the Roya Society, the Paris Academy of Sciences, the U.S National Academy of Sciences, the Academy o Sciences of Moscow, etc.

(12) Assist the work of other international organizations, such as the United Nations Food and Agriculture Organisation, the International Labour Office, the International Health Organisation, the United Nations Relief and Rehabilitation Administration, etc., in scientific questions.

At first sight this seems to need no comment since the means of mutual assistance would grow up naturally between these bodies. But mention may be made here of certain bodies which may play a very important part in world science without being international in the widest sense. Thus the British Commonwealth, now the War is practically over, wil almost certainly possess a science co-operation service of its own, with a central secretariat in London and permanent offices in all the other capitals, for example Delhi, Canberra, Ottawa, etc. This would be a federation within a federation, and its existence would enormously lighten the work of scientific co-operation since the British Commonwealth could be treated as one unit. The United States and U.S.S.R. do not present such problems on account of their territorial contiguity and unity.

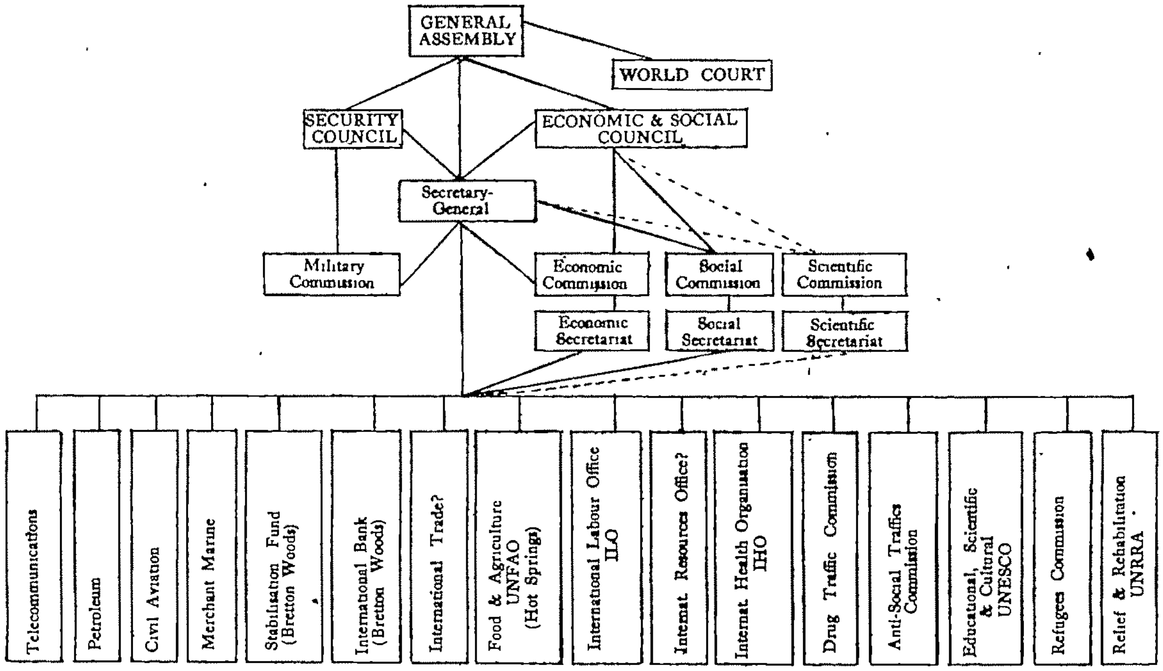
In the field of agriculture, what is essentially a British Commonwealth science co-operation service has led an extremely successful existence since 1929 under the name of the Imperial Agricultural Bureaux

(13) Combine into branches of one organization, i feasible, the smaller international scientific bodies already existing.

A Scientific Commission and Secretariat

In all the foregoing discussion, it has been assumed that the principal place for science in the international scheme would be the United Nations Educational and Cultural Organisation But although this body has seemed the obviou home for an International Science Co-operation

UNITED NATIONS WORLD ORGANISATION



GENERAL ASSEMBLY
WORLD COURT
SECURITY COUNCIL
ECONOMIC & SOCIAL COUNCIL
Secretary-General
Military Commission
Economic Commission
Social Commission
Scientific Commission
Economic Secretariat
Social Secretariat
Scientific Secretariat
Telecommunications
Petroleum
Civil Aviation
Merchant Marine
Stabilisation Fund (Bretton Woods)
International Bank (Bretton Woods)
International Trade?
Food & Agriculture UNFAO (Hot Springs)
International Labour Office ILO
Internat. Resources Office?
Internat. Health Organisation IHO
Drug Traffic Commission
Anti-Social Traffics Commission
Educational, Scientific & Cultural UNESCO
Refugees Commission
Relief & Rehabilitation UNRRA

Service, it must be remembered that a considerable number of men of science will be working with the other functional organizations, such as the envisaged Radio Communications Organisation, the Civil Aviation Board, the Food and Agriculture Organisation, the Petroleum Board, the International Health Organisation and the Drug Traffic Commission.

Another proposal, of great importance, therefore deserves discussion. The services which science could render to world organization are so substantial, and at the same time so unpredictable, that it might be desirable to introduce a scientific body at a higher level than any one of the functional organizations.

Let us look for a moment at the Dumbarton Oaks proposals (see accompanying diagram). From the General Assembly there will stem on one hand the Security Council for military and political matters five great Powers *ex officio* and six elected governments). This will not immediately concern us further. On the other hand, there will stem the Economic and Social Advisory Council (eighteen governments elected freely by the Assembly). This Council is to have an Economic Commission and a Social Commission with their respective secretariats "and such other Commissions as may be necessary". Why hould it not also have a Scientific Commission and Scientific Secretariat ?

A World Conference of Science

There can be no doubt that among those concerned with government and international relations there is general desire to see science well represented, and in a manner satisfactory to its representatives. The various proposals in this memorandum are brought orward as an aid to discussion. Others have been, and will be, forthcoming. There is available much arefully thought-out material embodying useful experience in crystallizing the structure of international organizations. But nothing authoritative can be obtained without a world conference of science, organized along the same lines as Bretton Woods, Hot Springs and Dumbarton Oaks. This should be called together as soon as possible. Only in this way can the voice of world science clearly indicate its wishes and aspirations with regard to the organization of the International Science Co-operation Service and the United Nations Educational and Cultural Organisation.

Summary

(1) An International Science Co-operation Service has been proposed. It is shown that there are immense tasks to be undertaken for the benefit of humanity through the rapid expansion and dissemination of knowledge, by such an organization.

(2) The United Nations Educational and Cultural Organisation now being planned could embody the machinery proposed above, subject to certain conditions being met. A formulation of the tasks before any science division of the United Nations Educational and Cultural Organisation is given.

(3) Science has so much to offer to world organization that it would be highly desirable if it were represented at the higher, or conciliar, level, as well as at the lower, or functional organization, level. A proposal is made for a Scientific Commission to take its place, with its corresponding secretariat, side by side with the Economic and Social Commissions and their secretariats, in assisting the work of the Economic and Social Advisory Council. This arrangement would provide a means for correlating the entire scientific work of the whole world organization, and affording means of contact between the men of science in the various functional organizations.

(4) In order to ensure that all arrangements made shall be to the greatest benefit of world science, and hence to the welfare of the peoples, it is necessary that a world conference of men of science and their organizations should be called to assemble at some convenient place as soon as possible.

PHYSICS AND ASTROPHYSICS AT THE IMPERIAL COLLEGE

By Prof. HERBERT DINGLE

DURING the past hundred years, the Colleges now amalgamated in the Imperial College of Science and Technology have been prominently associated with both the dissemination and the acquisition of knowledge in the physical sciences. The Royal School of Mines numbers among its professors of physics men like Stokes (1854–60) and Tyndall (1860–68), whose names stand in the forefront of Victorian physics and whose influence on their students, less easy to appraise than their personal contributions to research, was no less important in the maintenance and development of physical science on both its theoretical and practical sides. Tyndall was succeeded by Guthrie (1868–86), whose creation of the Physical Society of London (now the Physical Society, one of the most active and influential scientific societies in the country) in 1873 places him among the greatest benefactors whom this department of science has known. The Society, which at first met in Guthrie's rooms at South Kensington, later met regularly at the Royal College of Science and still continues frequently to do so. Its membership has a steady source of supply in the graduates of the College, and the association indeed is so intimate that there is scarcely an activity of the Society in which the College cannot claim some measure of participation.

A comparable influence is that of Mr. (later Sir) Norman Lockyer who, by his founding of *Nature* in 1869, provided a much-needed medium through which men of science could communicate to one another and to the world generally the results of their researches. After fifty years of continuous service, Lockyer passed on the office of editor to his former pupil Gregory (now Sir Richard Gregory, Bart.) who received his early training, and later assisted with the teaching, at the Royal College of Science. Gregory edited *Nature* for twenty years, so that for seventy of the last hundred years it may be said in this place without lack of modesty that the leading scientific journal of the world was established and guided by men whose scientific activities are part of the history of the Royal College of Science.

When, in 1868, Lockyer sprang overnight into fame by the dramatic circumstances of his discovery of the nature of solar prominences and the consequent birth of the science of solar physics, he was not a member of the College staff but a clerk in the War Office. He immediately established relations, however, with the College which he was later to adorn by entering into collaboration with Frankland, then professor at the College of Chemistry in Oxford Street, the foundation of which in 1845 makes the present year the centenary year of the Imperial College*. Lockyer had observed in the spectrum of the solar prominences and of the chromosphere, which he discovered and named, the lines of hydrogen and also an unknown yellow line which he was anxious to identify. He realized at once that thenceforth astronomical and laboratory observation must go hand in hand, and with Frankland's assistance he inaugurated a programme of research of the type which is now universally recognized as indispensable to the successful study of astrophysics. They worked in the evenings —the only time during which Lockyer was free—with the assistance of two young men, Pedler and McCleod, who later themselves became distinguished as Sir Alexander Pedler and Prof. H. McCleod. The physical conditions in the chromosphere were deduced from the characteristics of the spectrum lines of hydrogen, in the light of the changes which had to be made in the laboratory to produce those characteristics. The yellow line, however, could by no means be produced, and Lockyer soon came to the conclusion that it arose from an unknown element, to which he gave the name 'helium'. Not for twenty-seven years was helium discovered on the earth; but in the meantime Lockyer had learned a great deal about its character from a study of its behaviour in the sun (other lines besides the yellow one were soon recognized as probably arising from the same source), and to-day it is generally acknowledged that the importance of helium in the scheme of things would be difficult to exaggerate.

In 1870, a Royal Commission under the chairmanship of the Duke of Devonshire was appointed to inquire into the means by which State aid could more effectively advance science and scientific instruction in Great Britain and Ireland. Lockyer was appointed secretary to this Commission, and as one result of its activities the Royal College of Chemistry and the Royal School of Mines were united under the name of the 'Normal School of Science' (later changed to 'Royal College of Science') and established at South Kensington. The Commission sat for five years, and in its final report it expressed the hope that "some arrangement may be made by which the services of Mr. Lockyer in the promotion of science may be secured to the country" The ultimate result of this recommendation was that the Solar Physics Observatory (now transferred to Cambridge) was created under Lockyer's direction at South Kensington, and he was appointed in 1881 as lecturer, and in 1887 as professor, in astronomy at the Normal School of Science. From that time unti his retirement from the College in 1901, the activitie of the Observatory and of the College were closely connected.

During this period the work at South Kensington stood in the forefront of astronomical physics. O Lockyer's two outstanding ideas, that of the 'meteoritic hypothesis'—the theory that the heavenly bodies originated in meteors the gradual aggregation and subsequent development of which constitute th evolution of the physical universe—has not stood th test of time; though in some respects—such as th deduction that stars, starting as cool bodies, becom hotter and pass through a maximum temperature to cool state again—it later received on independen grounds a degree of approval for which Lockye fought vainly in earlier years. The other idea, however—that of 'dissociation'—was truly prophetic. O spectroscopic evidence Lockyer argued, with complete justification, that we must recognize that atom and molecules are not eternally unchangeable entities, but that they can be and are broken up int simpler forms which yield different spectra. Th character of the dissociation it was scarcely possib to conceive in the absence of any theory of atom structure; but on the main point, Lockyer, thoug he stood almost alone, was perfectly correct.

From 1885 onwards Lockyer had as his assista Alfred Fowler, a young student of great ability astronomical and spectroscopic work. Fowler su ceeded Lockyer in the conduct of the work at the Royal College of Science, and immediately distinguished himself by a succession of identifications of previously unknown features of celestial spectra. The TiO bands in the spectra of red stars, the CO bands in the spectra of comets' tails, and the 'cosmic hydrogen' lines are outstanding examples. Fowler's real opportunity came, however, when in 1913 Bohr initiated the modern theory of the origin of spectra. Fowler's familiarity with the spectra of the elements and their variation with physical conditions was unrivalled, and he immediately saw in the Bohr theory the explanation of facts with many of which he alone was acquainted. What Lockyer had described as 'dissociation' was now seen to be 'ionization', and the successive spectra of an element which Fowler had sorted out and classified on experimental grounds were identified as spectra of atoms at successive stages of ionization. As the theoretical possibilities of analysis developed, Fowler applied them to his store of experimental data, and for some years the College made outstanding contributions to the most rapidly developing and fundamentally important branch of physical research. Pupils came from various parts of the world, as well as from among College graduates, and, to mention but two examples, Saha's thermodynamical theory of stellar atmospheres and Catalan's discovery of the existence of multiplets originated in Fowler's laboratory. Experimental spectroscopy may truly be said to have been born and matured at the Royal College of Science. Fowler himself, after his appointment as one of the first Yarrow research professors of the Royal Society, continued to work and direct research there.

---

* See also *Nature* of Nov. 3, pp. 518–527.

Another branch of study in which the College has figured prominently is that of colour physics. This was begun as early as 1877, when Captain (later Sir William) Abney set up his laboratory in one of the temporary buildings at South Kensington which at that time were the only accommodation available to the Normal School of Science. The work has continued until the present time, and now forms an important part of the College's contribution to physical research. Abney's colour-patch apparatus was a pioneering effort in experimental research in this field, and it was applied not only to fundamental investigations but also to the testing of the colour vision of recruits for the Royal Navy and other services in which this physical characteristic is of importance. In photographic work also, particularly in the infra-red, Abney was a pioneer, and his emulsions for this region of the spectrum still defy reproduction. If the story that he photographed a kettle of boiling water in the dark by means of its temperature radiation is authentic, it was at the College that the work was done. In more recent years the Abney apparatus has been superseded by the Wright colorimeter, also a product of the College, and active research is carried on not only into the peculiarities of various types of colour vision, in which valuable assistance is given by the Medical Research Council, but also into many aspects of colour which affect problems of illumination and the dyeing and other industries.

For twenty-one years, from 1876 until 1897, the College was the scene of activity of one of the great experimenters of the time—Mr. (later Sir) C. V. Boys. Of his numerous achievements, all bearing the stamp of great ingenuity and experimental skill, it will be sufficient to recall his determination of the constant of gravitation with a small laboratory apparatus; his invention of the radio-micrometer, the most sensitive instrument yet devised for the detection and measurement of radiant energy; the production and discovery of the properties of quartz fibres which he made by firing white-hot molten quartz with an arrow from a bow; and the photography of lightning and of bullets in flight. All Boys's work was characterized by the combination of extreme accuracy and sensitivity with compactness of design. His genius was essentially individual and there was no possibility of his founding a school; but he had a keen eye for choosing the right man for a job, and he established a tradition which extends his influence beyond the direct effect of his own achievements.

During the earlier part of the present century, the Physics Department was under the direction of the late Prof. H. L. Callendar, whose work in temperature measurement and various other branches of heat and thermodynamics has become classical. The present chairman of the Governing Body, Lord Rayleigh (then the Hon. R. J. Strutt), was also at that time a professor of the College, and carried out much of his well-known work on radioactivity and discharges in gases. Callendar, like Boys, had a genius for exact measurement, and under his guidance and that of his collaborator, Prof. W. Watson, a succession of students received a training in habits of precision which has had no small influence on the successful application of physics to industrial affairs during the last forty years. It would be difficult to estimate, for example, how much Callendar's example and influence have contributed to the achievements of the National Physical Laboratory since its establishment. Some of the most outstanding members of the staff of that institution owe their physical knowledge and methods of research to his training.

During Callendar's professorship, the practice was begun of establishing sub-departments of the Physics Department for the advancement of certain specialized subjects. Astrophysics, already mentioned, became after Lockyer's retirement one such department which is still very active, and a Technical Optics Section was later added. This Section originated during the War of 1914–18 as a separate department, intended to be a source of production of optical designers, the lack of whom in the country during the War was felt as a serious disability. It was later brought under the general control of the head of the Physics Department, and it now covers a wide field of research and training in various aspects of optical work. An associated sub-department of Instrument Design has performed a useful function, and its reorganization as an independent department is now under consideration. Meteorology has pursued the opposite course to technical optics. Beginning in 1920 as a branch of physics, with a part-time chair, which has had such distinguished occupants as the late Sir Napier Shaw and Sir Gilbert Walker, it became a separate department in 1934 with a full-time professorship. Courses are given to students who have graduated in physics at the College or have had an adequate training elsewhere, and research into various problems of climate and weather is carried on. The most recently established sub-department is that of Geophysics, where, in the only postgraduate school of its kind in the country, students are trained in the principles of prospecting and other geophysical work.

Under the present head of the Department of Physics, Sir George Thomson, research in electron diffraction and nuclear physics is conducted. This is so much a matter of common and vital interest at the present time that it needs no emphasis here. The work of the College was specifically mentioned in Mr. Churchill's original statement on the atomic bomb, when for the first time the leading part played in the matter by Sir George Thomson's Committee was made known. Physics at the Imperial College begins its second century in most auspicious circumstances, and, granted the support to which its record entitles it, the future should witness no abatement of its influence both in pure research and in the application of physical knowledge in the widest possible field.

NEWS and VIEWS

Atomic Energy and Scientific Freedom

SINCE the opinions on atomic energy expressed in the leading article beginning on p. 547 were written, several important pronouncements in this connexion have been made. In the past, statements have been published from many sources and some of these, especially those attributed to Mr. Truman, have not only misled the general public, but have also caused irritation to many men of science in general and those who have kept in touch with research in atomic physics, especially since 1934, in particular. M. Molotov's claim in his speech in Moscow, on November 6, that the Soviet Union will soon "have atomic energy and many other things" will come as no surprise to men of science. On the other hand, it will probably stimulate second thoughts in others (and there are many) who have been inspired to believe that while the so-called 'secrets' of the atomic bomb remain vested in Britain, the United States and Canada, the world is safe.

Prof. M. L. Oliphant's vigorous speech at Birmingham on November 3 was also timely. As he stated, it is not possible to "deal with this job by a secret meeting between Mr. Attlee and President Truman. This is so big, so important, and so vital to the world, that it has to be done in the open". The recent statement from the Soviet Union confirms Prof. Oliphant's view that the value of the 'secret' held by the Allies is about six months effort on the part of any industrial country. A more vigorous and concerted effort on the part of all men of science to keep science free and intercourse between men of science open and world-wide is essential if the science of atomic energy, and most probably other branches of science eventually, are not to sink into the slough of international political intrigue. Science must not be allowed to become a tool in the hands of anyone, certainly not a part of any nation's foreign policy, for if ever it does then the consequences may prove to be the most serious in the history of science, indeed of the world.

At a joint conference of the World Unity Movement and the Council for World Airways (both organizations with offices at 20 Buckingham Street, London, W.C.2) held at the City Literary Institute, London, on November 2, Sir Leonard Hill, Prof. Lancelot Hogben, Dr. Kathleen Lonsdale, Prof. Lionel Penrose and Mr. Ritchie Calder, among others, spoke on the implications of the recent developments of atomic energy in relation to international affairs and the freedom of science. The following resolution, moved by Mr. Caradog Jones, was passed by the meeting: "Believing that no scientific knowledge should or can willingly be kept secret this Conference urges that the development of atomic energy be made subject without delay to international control and that the advice and co-operation of scientists be sought in order to devise the best means to exploit its use under a world authority solely and fully in the interest of the world community".

Nobel Laureates in Medicine

MEN of science will welcome the announcement that the Nobel Prize for Medicine for 1945 has been awarded jointly to Sir Alexander Fleming, Sir Howard Florey and Dr. E. Chain. Sir Alexander Fleming is now professor of bacteriology in St. Mary's Hospital Medical School, London. During the First World War, when he was working upon the bacteriology of septic wounds, Fleming became convinced that the chemical antiseptics then in use were often very harmful to the leucocytes which attack bacteria, and he discovered, in 1922, lysozyme, an antibacterial ferment which occurs in many animal tissues and secretions. In 1924 he showed that, if the antileucocytic power of an antiseptic is greater than its antibacterial power, it is not likely to be therapeutically valuable. When, therefore, he published in 1929, six years before the announcement by Domagk of the discovery of the sulphonamides, the discovery of penicillin and an account of his early trials of its antibacterial action, it was evident that he had provided us with an antibacterial agent which was not only powerfully antibacterial against some of the most pathogenic of organisms, but was also not toxic to the all-important antibacterial leucocytes and also not toxic to the animal infected with them. Attempts made at that time, however, to extract a form of penicillin which could be used therapeutically were not successful, and it seemed that this remarkable antibacterial agent would be denied to man.

The stage had, nevertheless, been set for the later work at Oxford of Sir Howard Florey and Dr. E. Chain, and it is interesting to note that the earlier work of these two investigators, like that of Sir Alexander Fleming, had predisposed them to make the particular and all-important contribution to the main problem which they made. Sir Howard Florey is now professor of pathology in the University of Oxford. Since the 1920's he has been interested in problems of bacterial inhibition, and he has studied Fleming's lysozyme. The original discovery that some organisms produce substances which inhibit or prevent the growth and multiplication of other organisms was made by Pasteur and Joubert in 1877, and in 1899 Emmerich and Loew had extracted pyocyanase from *B. pyocyaneus*. When the Oxford work on antibiotics began in 1938, pyocyanase and penicillin were selected for study. Florey now had at hand the assistance of Dr. E. Chain, University demonstrator in chemical pathology at the Sir William Dunn School of Pathology, a man whose studies of enzymes and of the isolation from natural sources of substances which are physiologically active has earned him distinction. Dr. Chain (though of Russian extraction) was born in Berlin and received his early training at the University there. He came to Britain in 1933 and was appointed to the staff of the Sir William Dunn School of Pathology in 1935.

The success of this collaboration is now well known.

ss well known—outside scientific circles, at any te—is the full story of the remarkable work of e team of experts which was afterwards formed Oxford for the study of the production, therautic use and mode of action of penicillin. Some y perhaps we shall have the human, as well as e scientific, story of this work and we shall then alize to the full the achievement of the many men d women who, working under the three leaders om the Nobel Prize so deservedly honours, have en to mankind, not only penicillin, but also the ole volume of the later work on antibiotics which s opened a new chapter in the history of the fight ainst disease. To these others their leaders have en acknowledged their debt.

nited Nations Educational and Cultural Organisation: Scientific Delegates

AMONG the delegates to the United Nations nference now meeting in London to discuss the tablishment of an Educational and Cultural ganisation (see pp. 553–561) are the following men science: *United Kingdom,* Dr. E. F. Armstrong, viser to the delegates of H.M. Government; *nada,* Dr. R. C. Wallace, principal of Queen's iversity, Kingston, formerly professor of geology d mineralogy in the University of Manitoba, and . J. G. Malloch, chief scientific liaison officer ondon) of the National Research Board of Canada; *nited States,* Dr. Harlow Shapley, director of Harvd Observatory (due to arrive shortly), and Dr. orge Stoddard, the child psychologist and comissioner of education for the State of New York; *ance,* Prof. Joliot-Curie and Prof. Auger, both ofessors of physics in the Sorbonne; Prof. H. ugier, professor of physiology in the Sorbonne, d Prof. Wallon, professor of psychology in the llège de France; *China,* Mr. Li Shu-Hua, physicist the Research Institute of Peiping, and Mr. Wang ng-Shi, director of the Chinese Institute of Psychoy, (the head of the Chinese delegation, the geologist . Chu Chia-Hua, is not likely to arrive in time); *therlands,* Prof. H. R. Kruyt, professor of physical emistry in the University of Utrecht; *Belgium,* of. G. Magnel, professor of civil engineering in the iversity of Ghent; *Norway,* Dr. Olaf Devik, ysicist, and Dr. Ellen Gladitsch, chemist; *Poland,* f. Mikolaj Olekiewicz, professor of biological and thematical statistics in the University of Lublin; *rkey,* Prof. Omer C. Sarc, professor of economics the University of Istanbul, and Prof. Ratip Berker, fessor of mechanical engineering in the University Istanbul.

w Television System

N October 31, Messrs. Pye, Ltd., gave a demonstra- at Cambridge of a new television system recently eloped by a research team under Mr. D. I. Lawson. novel feature in this system is the utilization of 'fly-back' times in the scanning sequence, during ich the transmitter would otherwise be idle, to ommodate short pulses the duration of which can modulated by the sound accompaniment of the vision programme. At the receiving end, these lth-modulated pulses are filtered out of the total nsmission by an amplitude-selection process. Thus ngle frequency channel is made capable of conveying h the vision and sound simultaneously; hence name 'Videosonic' which has been given to the tem.

With the standard type of 405-line scanning in use in Britain before the War, the fly-back time is 10 microseconds, occurring 10,125 times a second. This pulse-repetition frequency limits the audio-frequency range to something less than a high-fidelity standard, but a subsidiary demonstration showed that a 1,000-line system would enable a very satisfactory audio-frequency range to be transmitted. The use of a single channel has obvious advantages in view of the demand for space in the radio spectrum, but from the commercial point of view the chief potential advantage of the 'Videosonic' system is the cheapening of television receivers. The system also offers some interesting possibilities for future development; in particular the location of twin pulses in the fly-back space could be used for stereophonic sound, and the superposition of a sequence of amplitude changes on the width-modulated pulses might be used as a means of controlling a triple-scanning sequence for television in colour.

Danish Research Expedition

ON November 1, the Danish research vessel *Atlantide* left Plymouth en route for the coast of West Africa. The ship left Copenhagen on October 3 and, after being held up by bad weather, reached Plymouth on October 30. The vessel, a three-masted schooner which once sailed under the well-known name of *Shenandoah,* is owned by the Danish sculptor, Mr. Viggo Jarl, who has lent her to the Danish Government for marine research and is paying all expenses. Dr. Anton Fr. Bruun of the Copenhagen University Museum, who has made many cruises in the *Dana,* is leading the expedition; he has with him two young Danish zoologists, Jorgen Knudsen of the Royal Danish Veterinary College, and Torben Wolff. The British Museum (Natural History) is represented by Dr. F. C. Fraser, and the vessel will pick up Dr. G. R. Howat, Government chemist, at Accra. The route to be followed covers the whole of the coast of West Africa to the Cape, and includes the Ascension Islands and St. Helena. The expedition is intended primarily to make a zoogeographical survey along that coast. Sections will be made outwards from the coast to deep water at intervals, the main region of interest lying between the Congo and Walfisch Bay, an area from which little collecting has been done. The vessel is equipped for collecting with Petersen and Feen grabs, shrimp trawls and plankton nets of various sizes; she also carries a small harpoon gun. The voyage is expected to last about eight months, and it is hoped that much valuable material will be collected for the Danish and British Museums. This is the first marine expedition to leave the coasts of Europe since the War ended, and the Danes are to be congratulated on acting so promptly in starting the exploration of the sea once more.

Queen Victoria Memorial, Salisbury, Southern Rhodesia

THE annual report, for the year ended March 31, 1945, of the Queen Victoria Memorial, Salisbury, Southern Rhodesia, indicates that owing to the difficult conditions with which publishers in Great Britain are faced, the limitation of the number o copies of books, and the irregular arrival of mails from overseas, the supply of books for the library continues to decrease. In the meantime, the demand for certain cultural and technical literature is being met so far as is possible, but no improvement in the position is expected for some considerable time to come. Of the Salisbury Museum, the Committee reports that in spite of difficulties relative to exhibition and working space, specialization in certain branches of science continues.

Summer School in X-Ray Crystallography at Cambridge

For the third year in succession, members of the Department of Mineralogy and Petrology and the Cavendish Laboratory at Cambridge were able, through the courtesy of Prof. C. E. Tilley and Sir Lawrence Bragg, to conduct a summer school in X-ray crystallography; the administration was under the control of the Board of Extra-Mural Studies. The first part of the course, which was attended by everyone, dealt with crystal symmetry and the use of stereographic and gnomonic projections. Then followed fundamental theory and practice in the interpretation of the various types of X-ray photographs, the production and properties of X-rays and the measurement of intensities of X-ray reflexions. The methods of taking, interpreting and using powder photographs were dealt with in some detail. The school differed from those previously held in that during the last two days it was divided into two groups (as it happened, into almost equal numbers), one of which studied further theory and practice in the elucidation of fundamental crystal structure, such as the theory of space groups, structure factors, use of absent spectra to determine space groups and parameter determination; the second group studied powder photographs in relation to metallurgical problems such as the determination of grain size, stress and the orientation of crystals in drawn wires and rolled sheets. Throughout the course the labour of computation was greatly reduced by the use of graphical methods and the provision of tables in which many of the factors in formulæ had already been worked out. Of the thirty-one who attended the course, eight were from universities, two from research institutes, one from a technical college, two from research associations, three from Government laboratories and fifteen from industry. The opportunity for interchange of ideas afforded (especially at tea served in the laboratory after the day's work) was one of the most valuable aspects of the course. The success of these schools at Cambridge should encourage other authorities to develop this aspect of university education.

Institute for the Study of Animal Behaviour

At a meeting of the Council of the Institute for the Study of Animal Behaviour on October 16, at the Zoological Society of London, Dr. E. Hindle, scientific director of the Zoological Society, was elected president in succession to Dr. E. S. Russell, who had resigned and who was made an honorary member and re-elected a member of Council. The following were also re-elected members of Council: Mr. R. J. Bartlett, Dr. J. T. Edwards, Mr. J. W. B. Douglas (*Hon. Asst. Editor*), Mr. J. M. McC. Fisher, Dr. J. Hammond, Dr. E. Hindle, Dr. J. Huxley, Dr. G. Lapage, Dr. W. H. Thorpe, Dr. A. Walton, Prof. A. N. Worden (*Hon. Secretary-Treasurer*), Prof. S. Zuckerman (*Hon. Editor*). Dr. A. Landsborough Thomson, Prof. James Gray, Dr. B. W. Tucker and Mr. David Lack were invited to attend to discuss Dr. W. H. Thorpe's proposal that a small field station for work on bird behaviour be initiated under the direction of the Institute. This proposal was welcomed, and Dr. Thorpe was entrusted with the pr paration of working details of his scheme. The futu of publication in Europe of matter relating to anim behaviour was discussed also in the light of a con munication from Dr. N. Tinbergen, of the Zoologic Laboratory of the University of Leyden. The Counc agreed to support any claims for the financing work on behaviour among domestic animals, f example, on grazing behaviour in ruminants and sexual behaviour in bulls. It was agreed to hold th next scientific meeting of the Institute early in 194

University of London

Dr. G. A. H. Buttle has been appointed to th University chair of pharmacology tenable at th College of the Pharmaceutical Society of Gre Britain as from October 1.

The following titles have been conferred: profess of electrical engineering on Dr. H. E. M. Barlo who has been reader in electrical engineering University College since 1938; reader in analytic chemistry in the University on Mr. L. S. Theobal in respect of the post now held by him at Imperi College of Science and Technology; reader i nutritional science in the University on Dr. Glad A. Hartwell, in respect of the post now held by her King's College of Household and Social Science.

Announcements

Dr. A. B. Stewart, deputy director of th Macaulay Institute for Soil Research, Aberdeen, ha been granted leave of absence for six or seven mont to advise the Government of India upon the orga ization and conduct of research and field experiment tion upon problems of soil fertility and crop pr duction. Dr. Stewart has in recent years devote much time to problems of soil fertility in relation t both plants and animals.

The Medical Research Council has appointed th following to be members of its Industrial Healt Research Board until August 31, 1948: Prof. F. Bartlett (*chairman*), Dr. A. N. Drury, Prof. Ferguson, Lord Forrester, Prof. A. Bradford Hi Dr. D. Hunter, Prof. Esther M. Killick, Prof. R. Lane, Prof. J. M. Mackintosh, Dr. E. R. A. Mer wether, Prof. J. A. Ryle and Mr. J. L. Smyt (Dr. R. S. F. Schilling, seconded to the Council headquarters staff from the Factory Department the Ministry of Labour and National Service, co tinues to be secretary of the Board.)

The directors of Messrs. H. K. Lewis and C Ltd. (Medical Publishers, 136 Gower Street, Londo W.C.1), are considering adding foreign medical a scientific books to their lending library. In order assess the possible demands for such books, questionnaire is being circulated to men of scien and medical men. Copies of this can be obtained fro Messrs. Lewis at the above address.

A Conference on "The Training, Qualificatio and Function of Dietitians" will be held by t Nutrition Society on November 17, beginning 11 a.m., at the London School of Hygiene a Tropical Medicine, Keppel Street, W.C.1. No members desiring to attend this meeting should app to a member of the Society for a ticket of admissio Further details of the Nutrition Society can obtained from the Hon. Secretary, Dr. Leslie Harris, Nutritional Laboratory, Milton Road, Ca bridge.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.

The Raman Effect in Rocksalt

THE theory of the Raman effect in crystals, as ound in the literature, is rather unsatisfactory. part from some general symmetry considerations, the only attempt known to us of establishing definite ormulæ is that by Fermi and Rasetti[1] who gave the orrect expressions in a general way for explaining the observations on rocksalt. These observations made by Rasetti[2] show clearly a continuous spectrum with small superimposed eaks. The theory mentioned explains this eneral aspect satisfactorily; but Fermi and Rasetti find the formulæ too complicated for uantitative discussion.

We have taken up the same problem again ecause these same observations have been used y Raman and his pupils as an argument against ttice dynamics and in favour of their own theory of lattice vibrations. The latter contends that a crystal lattice has a vibration spectrum f a small number of frequencies, in contradiction to elementary laws of classical or quanum mechanics, according to which the number f vibrations of a system of N particles is $3N$, ence quasi-continuous for a crystal of finite imensions (N large).

Krishnan[3] interprets Rasetti's published reroduction of the Raman spectrum as a line pectrum of nine Stokes lines (and nine anti-Stokes lines), neglecting the very strong background ffect. This is rather strange, since the publication of he Italian authors also contains a photomicrograph f the density distribution, which shows that the ontinuous background is an essential feature. The riginal picture is reproduced herewith (Fig. 1).

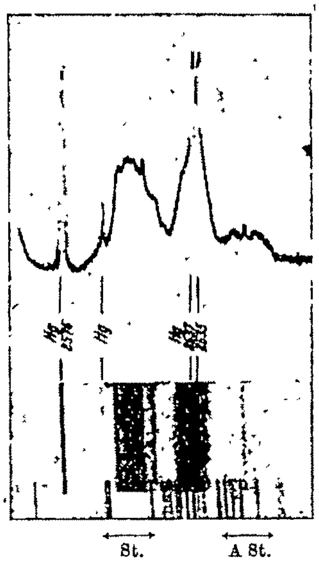


Fig 1. LOWER: PHOTOGRAPH OF RAMAN SPECTRUM SHOWING FAINT LINES ON BACKGROUND. ST, STOKES LINES. A.ST., ANTI-STOKES LINES. UPPER PHOTOMICROMETRIC CURVE OF INTENSITY DISTRIBUTION, SHOWING THAT THE APPARENT LINES ARE SMALL PEAKS ON A STRONG BACKGROUND

Krishnan further states that the number of lines (nine) is in agreement with Raman's theory; but he makes no attempt to compute the frequencies and intensities of these nine 'lines'.

In these circumstances we thought it necessary to work out the complete theory of the Raman effect in crystals and apply it to the case of rocksalt. This substance is particularly suitable, as Kellermann[4] has worked out the vibration spectrum in detail. His numerical results are independent of any arbitrary constants and are based only on the measured values of the lattice constant and compressibility. Using these results, we have derived the Raman spectrum, which is in this case a second-order effect with respect to the amplitudes of vibration, and we present the results in Fig. 2.

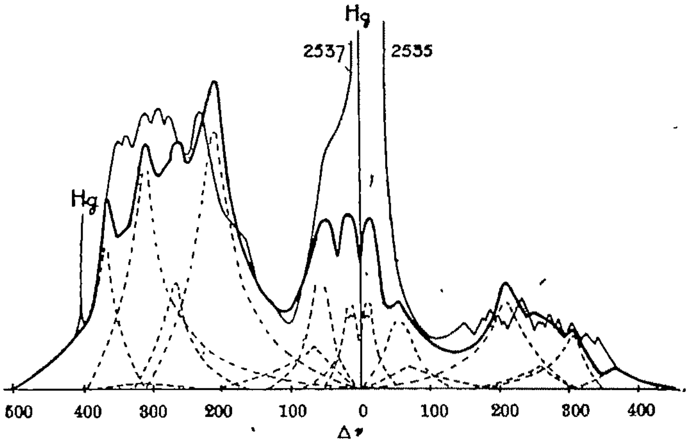

Fig. 2. FINE LINE REPRESENTS FERMI-RASETTI PHOTOMICROGRAPH (FIG. 1). BROKEN LINES ARE APPROXIMATE THEORETICAL CONTRIBUTIONS FROM PAIRS OF FREQUENCY BRANCHES. THICK LINE IS THEORETICAL CURVE FOUND BY SUPERPOSITION OF THESE.

It shows that the general features of the observations (continuous background with small peaks) come out very well from the theory. The range of the continuum and the positions of the maxima are obtained without any arbitrary assumptions, while the intensities are fitted to the experiment by adjusting some coupling constants. The formulæ for the intensities are so involved that we have picked out only the main terms. It is quite possible that further careful study would improve the agreement.

The Indian physicists have published new and valuable observations of a similar kind (on Raman effect and other optical phenomena in crystals) and have interpreted them as evidence for their theory. We are convinced that ordinary lattice dynamics will be able to explain these facts in a satisfactory way, though the calculations may be involved.

[3] Krishnan, R. S, *Proc. Ind. Acad. Sci.*, A, 18, 298 (1943).

[4] Kellermann, E W., *Phil. Trans.*, A, 238, 513 (1940).

The Editors, on receiving our communication, sent us the proofs of a new note by Prof. Krishnan on the same subject published in *Nature* of September 1.

It contains a reproduction and description of a new photograph which is certainly a considerable improvement on Rasetti's work. Krishnan interprets it in the same way as before, that is, as a line spectrum, because the little peaks, already visible in Rasetti's photomicrograph, have come out more clearly; but he again neglects the continuous background.

We have nothing to change in our opinion and only wish to add a few remarks. In the new photograph Krishnan finds six stronger and two weaker peaks; he seems to have given up the claim that the observations confirm the prediction from Raman's theory of exactly nine lines. In our theory the 'lines' are the density maxima of the combinations in pairs of the six branches of the frequency (six of the type 2ω, fifteen of the type $\omega_1 + \omega_2$, fifteen of the type $\omega_1 - \omega_2$); our figure contains only a few of these, which by adapting three coupling constants turn out to be the strongest. The superposition of these branches gives a most satisfactory qualitative picture of the observed curve; to reach perfect agreement a much better knowledge of the vibrational spectrum would be needed than is given by Kellermann, as well as sharper approximations in working out the complicated formulæ. This does not seem to be worth while.

Concerning the infra-red absorption lines mentioned by Krishnan, the explanation given by Born and Blackman is only partly correct; the weak lines are indeed the density maxima of some of the pairs of branches, but the appearance of this combination spectrum does not depend on anharmonic terms in the equation of motion, but follows directly from the deformability of the ions, in the same way as the second-order Raman effect.

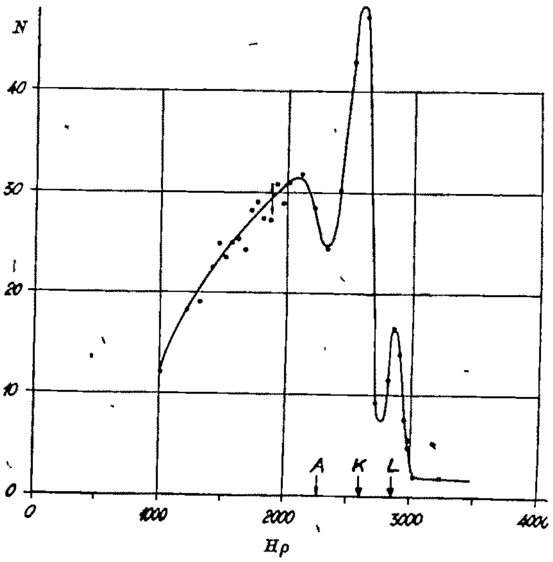
Radioactivity of Active Nitrogen

INVESTIGATIONS of the radiations from the artificially active elements have been made with the help of the lens β-spectrograph, previously described[1]. It is of special interest to examine the β-spectra from the light elements, which, on account of their positions in the Sargent diagram, are due to permitted transitions. Among those elements there are only two, which, considering the short half-lives we have to deal with here, can be investigated with such an accuracy as to permit any conclusion, namely, carbon C^{11} and nitrogen N^{13}. Of these elements C^{11} has already been the subject of an investigation with the lens-spectrograph[2]. Nitrogen[3] is of special interest because of the fact that several authors[4] have found that the positron radiation is accompanied by a γ-radiation, caused by a complexity in the β_+-spectrum. On the other hand, some investigators[5] have not been able to detect this γ-radiation.

In order to study N^{13}, graphite was bombarded with deuterons (5 MeV.) in the Stockholm cyclotron. The half-value period for the active nitrogen was determined as 10·13 ± 0·10 m. by means of a Geiger-Müller counter plus a scale of eight, and also by an ionization chamber plus electrometer, the results obtained by the two methods showing good agreement. With the help of a special lock-device, the rather short-lived sample could quickly be brought into the β-spectrograph. To get a correct form of the energy distribution curve, it is important to avoid secondary radiation so far as possible. The window in front of the Geiger-Müller counter was less than 0·5 μ, which permitted an almost true reproduction of the spectr without any corrections for absorption even at ve small energies. The result from eleven differe series of measurements of the positron spectrum w plotted in a diagram. A separate investigation the upper limit was also made. This limit was determined as 1·24 ± 0·02 Mev.



In the Fermi formula for the energy distributio of the β-spectrum, there is a function $F(ZW)$, whic accounts for the influence of the Coulomb field of th nucleus upon the disintegration. It may be show that this function for light nuclei is approximate with good accuracy by $(1 - 1{\cdot}65\Delta^2)\, e^{\pi\Delta}$, whe $\Delta = \alpha Z \frac{W}{p}$, α is 1/137, W is energy, p momentum, Z is atomic number (with negati sign for positron emission). The Fermi diagram cu the abscissa at $W_{\text{max.}} = 1{\cdot}24$ Mev., in good agreeme with the direct determination. The departure fro the straight line occurs at $W = 0{\cdot}47$ Mev., a poi which evidently might correspond to the upper lim of the component with lower energy if the β_+ spectrum were complex. If we make a computatio of the transition probability according to the actu β-theory based on the fact that the lowest state o N^{13} and of C^{11} is a $^2P_{1/2,\,3/2}$-state we find, however, tha the intensity for the supposed component of lowe energy, if it exists, would amount to an almos negligible fraction of the component with the highe energy, due to the large difference between the uppe limits for the two components that our measurement would require. The departure from the straight lin might in fact be explained mostly by the inevitab secondary radiation, which originates in the sampl itself. If we plot $\left(\frac{N}{pW}\right)^{1/2}$ against $\sqrt{1 + p^2}$, w get, however, an absolutely straight line, whic furthermore cuts the abscissa at the same poi $W_{\text{max.}} = 1{\cdot}24$ Mev. Such a diagram might possibl be of use in attempts to separate the component in a really complex spectrum, when the sample are not exceedingly thin.

The illustration shows the result of an investigatio of the photo- and Compton-effect with lead as secondary radiator in the spectrometer. The curve show from the left to the right: the Compton effect for th annihilation radiation, the *K*- and *L*- photo-lines from the same radiation. The energy for the annihilaion radiation obtained from the curve is 0·515 ± 0·010 Mev., in good agreement with the value, which can be computed from mc^2, namely, 0·511 Mev. No γ-ray of the previously[4] reported energy of 80 kev. has been found by us, and according to our investigation the only γ-ray which accompanies he disintegration is due to the annihilation radiation.

Temperature Effect on Ultra-sonic Velocity in Water

VERY few systematic data exist so far relating to the effect of temperature on ultrasonic velocity in liquids, especially water. Loomis and Hubbard's results[1] for the change of ultra-sonic velocity in water and other liquids with rising temperature may be ited as perhaps the only systematic investigations, because earlier experiments[2] were carried out under rather unstandard conditions and in a very low region of sonic frequencies and therefore are not reliable. Even Hubbard's data for water are reported for a ery limited range of temperature, 0°–40° C., using a sonic interferometer at a frequency of 500 kc. only. The present work extends the knowledge of ultrasonic velocity in water up to a temperature of 70° C., using the method of diffraction of light by ultrasonics at a frequency of 5·7 mc./sec.

In this investigation the ultra-sonics were produced by a quartz crystal (diam. 22 mm., fundamental frequency 1·91 mc./sec.) which was cut and ground in this laboratory by me. The crystal was excited to its third harmonic at a frequency of 5·7 mc./sec. by applying the output from a one-valve oscillator (Hartley circuit), adjusted to the same frequency, to the two opposite faces of the crystal. For the production of ultra-sonics in water under investigation, the crystal was not directly immersed in water because of short-circuiting. The crystal was mounted in a small metallic cell containing xylol and having a nall leak-tight mica window in one face to let ultra-sonics pass through it. The cell containing the quartz crystal and xylol, and thus serving as a sort of source of ultra-sonic waves, was placed along one of the walls of a rectangular plate-glass vessel containing distilled and degassed water.

The plate-glass vessel with its contents was surrounded by a water-bath the temperature of which could be controlled and kept constant within 0·1° C. by a simple thermostat and relay; the water-bath was constantly agitated by stirrers, and the whole bath was enclosed in a double-walled wooden box loosely packed with sawdust. The temperature was read directly by a sensitive thermometer dipped in the plate-glass vessel.

The bath with its outer wooden enclosure had glass windows on two opposite faces which allowed parallel monochromatic light (green line λ = 5461 A. from a mercury arc) to pass at an incidence perpendicular to the direction of ultra-sonics generated in the vessel. A long focal length lens (f = 110 cm.) placed on the other side focused the emergent beam on a photographic plate which recorded the diffraction pattern for various temperatures of the water. Corresponding to each temperature from about 31° C. to 70° C. at intervals of 5° C., six independent photographic exposures were taken, and a mean of these six readings was used for calculation of the velocity at that temperature. Diffraction patterns were also recorded for temperatures at 75° C. and 80° C.; but these were too diffused, due to the constant shifting of density layers, to admit of any measurement without a considerable error.

The ultra-sonic intensity was kept fairly low (so that usually only two orders of diffraction appeared) in order to avoid the heating up of the liquid which results at higher intensities and disturbs the constancy of temperature.

The ultra-sonic velocity in water at various temperatures was calculated by comparing the distances of diffraction orders with those of pure xylol (Merck's) found with the same apparatus. The ultra-sonic velocity in xylol is a good standard, as almost every worker in the ultra-sonic field has worked it out independently; and hence the velocity is known to a fair degree of accuracy at several temperatures and frequencies.

The velocity in water at the various temperatures was found to be as follows:

ULTRA-SONIC VELOCITY IN WATER (FREQ. 5·7 MC./SEC.)

No.	Temperature ° C.	Ultra-sonic vel. (author) m./sec.	Ultra-sonic vel. (Hubbard) m./sec.
1	31·5	1510	1509·0 (at 30° C.)
2	35·1	1521	1520·6 (at 35° C.)
3	40·1	1531	1530·3 (at 40° C.)
4	45·4	1538	—
5	50·5	1545	—
6	55·4	1552	—
7	60·3	1553	—
8	65·3	1555	—
9	70·3	1557	—

My thanks are due to Prof. P. K. Kichlu for his interest in the work.

Near Ultra-Violet Emission Bands of Benzene

THE ultra-violet emission spectrum in the region 3000–2475 A., obtained by Asundi and Padhye by high-frequency electrical discharge through benzene vapour[1], is probably more closely similar than the authors have realized to the fluorescence spectrum excited by Hg 2537 A. in benzene vapour at pressures which are not too low[2].

The authors point to a supposed difference of relative intensity in the various progressions labelled

A-F, giving the order *B, F, D, A, C* for the electrical, and *C, A, B, E, D* for the optical, method of excitation. Some confusion has, however, arisen, and it may be due to the fact that, when Sponer, Nordheim, Sklar and Teller[3] suggested their new basis for assignments in the ultra-violet spectra of benzene, they very properly changed Ingold and Wilson's labels. In any event, there appears to be no difference in the order of the intensities, which in both spectra agrees with the Boltzmann factors associated with the progressions.

The other supposed difference relates to the apparently shorter sequences in 160 cm.$^{-1}$ which appear in the electrically excited spectrum. However, the recognition of the nature and classification of the upper electronic state permits an assignment of fluorescence bands which avoids the assumed long sequences in 160 cm.$^{-1}$; and it now appears that with either type of excitation the upper electronic state is able to settle to something like a true Boltzmann distribution with respect to vibration and rotation. These and related matters will be discussed *in extenso* elsewhere.

Spectra of Diatomic Oxides by the Method of Exploded Wire

DURING recent years we have developed the method of the exploded wire with the view of its application to the study of molecular spectra, but the circumstances of the German occupation have prevented us from publishing the results. A full account of our investigations by this method (as well as by the method of the aureole of an arc) of FeO, NiO, CoO, CuO and CaO spectra will be given later in the *Bull. Soc. Roy. Sci. Liége*.

FeO. We studied the spectrum of FeO in the yellow during 1940 in collaboration with A. Delsemme, and extended our investigation to the blue and the photographic infra-red during 1942 with L. Malet. Four systems can be represented by:

$$\begin{array}{llr}
\nu = \left\{\begin{matrix}17908\\17808\end{matrix}\right\} - 875\,v'' + 5\,v''^2 + \left\{\begin{matrix}667\\660\end{matrix}\right\} v' & & \text{(System } A\text{)}\\
\nu = 17267 - 875\,v'' + 5\,v''^2 + 825\,v' & & \text{(System } B\text{)}\\
\nu = 22326 - 875\,v'' + 5\,v''^2 + 540\,v' & & \text{(System } C\text{)}\\
\nu = 12900 - 955\,v'' + 670\,v' & & \text{(System } D\text{)}
\end{array}$$

Two short isolated band series ending on the same lower level as the *A*, *B* and *C* bands indicate the existence of FeO electronic terms at 12,150 and 14,650 cm.$^{-1}$ above this level, which is probably the ground-level of FeO. The classification of the yellow doublets is the same as that proposed by Gaydon and Pearse[1].

NiO. We studied the spectra of NiO and CoO with L. Malet in 1942. For NiO nearly all the bands observed between 9,070 and 4,145 A. can be fitted into six systems. The constants are given in Table 1.

TABLE 1.

	ν_0	ω''	ω'
System I	12655	615	475
System II	13688	590	460
System III	16420	615	560
System IV	19314	825	590
System V	19602	820	590
System VI	21185	825	570

The state with $\omega'' = 615$ cm.$^{-1}$ is probably th ground-state of the molecule. The systems II, I and V are established with less certainty than th others.

CoO. Bands are observed between 5,000 an 10,000 A. The only characteristic frequency ω'' = 840 cm.$^{-1}$ can be attributed with great probabilit to the ground-state of the molecule.

CuO. The spectrum of CuO was investigated du ing 1942 in collaboration with J. M. Lejeune. Th vibrational analysis of the red CuO bands showe that they can be represented by:

$$\nu = 16222 - 625\,v'' + 3\,v''^2 + 274\,v' \quad \text{(System I)}$$

The green and blue bands observed previously b Hertenstein[2] can be represented by:

$$\begin{array}{lr}
\nu = 21570 - 625\,v'' + 3\,v''^2 & \text{(System II)}\\
\nu = 21824 - 625\,v'' + 3\,v''^2 + 510\,v' & \text{(System III)}
\end{array}$$

The lower state with $\omega'' = 625$ cm.$^{-1}$ is very prob ably the ground-state of the molecule.

CaO. This spectrum has been studied during 194 and 1944 in collaboration with J. M. Lejeune. Th main results are summarized in Table 2, which in cludes also the revised results of previous investig tions on this spectrum.

TABLE 2

	System α (Meggers I)	System β (Meggers II)	System γ (Orange bands)	System δ (Green bands)	System ε	System σ	Syste η
ν_e	9491	13679	15947	18260	25191	28054	293
ω''	637	711	640	780	711	711	
ω'	674	694	711	670	575	550	8.
$x''\omega''$	~7	~3 5	~5		~4	~4	
$x'\omega'$	~5	~5	~5				

The state with $\omega'' = 640$ cm.$^{-1}$ is probably th ground-state of the CaO molecule.

All the proposed ω''-values for the ground-stat of the molecules studied are in accordance with th empirical laws governing the ω''-values of diatom oxides.

The results of our investigation on the AlO spectru by the method of exploded wires, which enabled us establish several new systems of AlO and to study some detail the predissociation phenomenon emission spectra, have already been published[3,4].

Chromatography of Two Solutes

WE regret that we cannot agree with the concl sions arrived at by Dr. Glückauf[1] and that even the case of the Langmuir isotherm they seem scarce plausible in the general case.

Our equations can be applied to any suitab adsorption isotherm. In the case of a single solu the concentration in the developed band is given our equation:

$$f'(c) = \frac{v}{x} \quad . \quad . \quad . \quad . \quad . \quad . \quad ($$

The corresponding equation for two solutes is:

$$\begin{vmatrix} f'_{c_1} - \dfrac{v}{x} & f'_{c_2} \\ g'_{c_1} & g'_{c_2} - \dfrac{v}{x} \end{vmatrix} = 0 \quad . \quad . \quad ($$

rom which the equation (3) of our note may be educed. (The plus sign in front of the square root f equation (3) of our communication should be eplaced by a minus sign.)

There is a second equation connecting c_1, c_2 in the eveloped band. This is equation (2) of our previous aper and it can be employed to find the level at hich the equation (2) given above begins to hold, hat is, the point where c_2 is zero. Now according o Glückauf, at this point dc_2/dc_1 is discontinuous. t follows from our theory that it is, in general, ontinuous and has the value zero. This we feel s physically more reasonable than the hypohesis of Dr. Glückauf. From this it follows that $g'_{c_2})_{c_1=0} = (f'_{c_1})_{c_2=0}$ and the complete theory as iven in our previous communication.

Under some special conditions and if some f the original undeveloped band is still present, may be possible that $\left(\frac{dc_2}{dc_1}\right)_{c_2=0} > 0$. This would seem o be the case discussed by Dr. Glückauf. However, here are other points in which our theory differs rom his even for this case, and we find ourselves nable to agree with his main conclusions.

A full discussion will be given in our forthcoming ublication.

A. C. OFFORD.
J. WEISS.

University of Durham,
King's College,
Newcastle-upon-Tyne.

See *Nature*, 155, 725 and 156, 205 (1945).

BY changing the sign in front of the square root f their equation (3), Prof. Offord and Dr. Weiss ave made this equation in substance identical with ay proposed equation (1.1), though the complexity f the differential functions tends to hide this fact rom the eye of the reader. As regards the "scarcely lausible" discontinuity at the rear of the mixed and, which is quite plausible to de Vault (1943), have convincing experimental evidence which will e published in due course.

The implied suggestion that the tail end of the ixed band can be influenced by the state of the ront boundary (whether developed, undeveloped r eluted) must be strongly repudiated both on heoretical and experimental grounds. The conitions of the diffuse back boundary depend on the itial concentrations independently of whether these re still present in the chromatogram or not.

A correct general solution must contain the correct olution of any special isotherm. Offord and Weiss's quations (6 and 7) when applied to the Langmuir otherm (using the notation of my earlier letter) ad to

$$V = b_1 m_1/\delta^2 \quad \text{(Offord and Weiss 7, Langm.).}$$

y corresponding equation, obtained by direct interation of the common equation (Offord and Weiss 2 r Glückauf 1) is

$$V = b_1 m_1(1 + \lambda)/\delta^2. \qquad \text{(Glückauf 9).}$$

hus, one of the two theories is wrong.

The apparently slight difference is of the greatest ractical importance. Contrary to equation (Glückauf), equation (Offord and Weiss 7, Langm.) would ean that the volume of developing solvent required r complete separation is independent of the conentration of the solutes in the developing solvent. No practical chromatographer will agree to that, especially for substances difficult to separate. Equation (Offord and Weiss 7, Langm.) would also require that V is independent of the quantity m_2. I have experimental proof that this is not so. Moreover, in the case of comparatively low adsorption intensities, ($b_1 c^0_1 \lll \delta$), the Langmuir isotherm must revert to the ideal case where Wilson's equation, $V = v^0/\delta$, is valid. As shown in my first letter, my equation (9) fulfils this demand, while equation (Offord and Weiss 7, Langm.) does not.

Finally, the laborious though not difficult graphical integration of $df/dc_1 = dg/dc_2$ has been carried out for several types of isotherms, using numerical constants. The results for the Langmuir isotherm are identical with those of my theory. All integrations show that Offord and Weiss's conclusions (reiterated in their second communication) are in complete disagreement with this fundamental equation from which their results are supposed to be derived.

Determination of β-Carotene in Dried Grass

AT the time when the tentative official method for the estimation of carotene in dried grass[1] was drawn up, it was recognized that it gave results which included one or more pigments other than β-carotene[2,3]. However, at that time there seemed little chance of working out a satisfactory process for β-carotene on account of difficulties in obtaining a suitable adsorbent; and in accordance with the usual custom it was decided to return the whole of the petrol-soluble phase as 'carotene'. Although it has been shown that β-carotene predominates, yet this may account for only 70 per cent or even less of the 'crude carotene'.

Mann[4] has proposed the use of the name neo-β-carotene for the major pigment of the remainder, in deference to Beadle and Zscheile[5], who propose this name instead of pseudo-α-carotene referred to by Carter and Gillam[6].

Mann had pointed out that this second major pigment of grass is not the pseudo-α-carotene of Carter and Gillam, and shortly after, Zechmeister[7] published data on the isomerization of the carotenoids in which he sets forth a method of nomenclature in which pseudo-α-carotene will fall into the category of neo-β-carotenes. Zechmeister shows these neo-β-carotenes to be true isomers of β-carotene entering into *cis-trans* isomerization by heat, by iodine catalysis, by acid catalysis and by the action of light.

Other workers[8,9] have found that such neo-β-carotenes have biological activity; these findings we believe reasonable to adopt in view of the fact that the neo-β-carotenes which they investigated were part of the β-carotene isomerization complex.

To avoid confusion in the literature and to conform to Zechmeister's new nomenclature, which regards neo-β-carotene as the name of a group of isomers, we propose that the previously mentioned other petrol-soluble 'carotene' pigments of dried grass should be termed 'spurious carotenes', and that the use of the name neo-β-carotene for the major component of those pigments should be discontinued. In support of this suggestion, it is to be noted that other workers[2,4,9,10] have encountered such petrol-soluble pigments which have shown negligible or no biological activity.

As both Mann and Zechmeister show that solutions of β-carotene tend to isomerize with heat or standing, and upon isomerization have a lowered molecular extinction coefficient with altered absorption maxima, we would direct the attention of workers to the necessity for the use of as little heat as possible in preparing β-carotene extracts of dried grass, and the further necessity for as rapid estimation as possible of the β-carotene in the solution.

Both of us have suggested the use of chromatographic methods for the separation of β-carotene from all other pigments occurring in dried grass[3,4], and we propose to communicate with other workers interested in this subject in order to promote examination of methods which may produce more concordant results than are obtained at present.

Preparation of Silicic Acid Jellies for Bacteriological Purposes

For the preparation of jellies intended for the cultivation of micro-organisms, agar-agar is generally used. For some purposes, however, it is desirable to have an opportunity of obtaining cultures of bacteria or fungi on inorganic gels to which only known substances are added. Agar-agar is an organic substance varying in composition and containing other organic substances, which may influence the cultivation of bacteria. Attempts have been made to prepare gels, for example, of silicic acid; sodium silicate and hydrochloric acid were used for the purpose[1,2,3,4]. But this method entails certain difficulties. Instead we have tried to make silica gels for bacteriological purposes from *ortho*-silicic acid tetramethyl ester, $Si(OCH_3)_4$. When water is added to this silico-compound, silicic acid and methanol are formed, and the solution is transformed into a firm coherent gel as clear as glass. This gel formation was observed by Grimaux[5].

The simplest method for the preparation of these gels is to autoclave a mixture of the silico-ester and a suitable nutrient solution in the usual way in a test-tube, in which the gel is formed, the tube being sterilized simultaneously. After the sterilization, the tube must not be cooled too fast as the gel is then apt to crack. The best way of avoiding bubbles and cracks during sterilization of the gel is to employ boiled water or boiled nutrient solution.

During the hydrolysis, however, methanol is formed, which does not completely disappear on aut claving and prevents more delicate bacteria fro growing. In order to enable such bacteria to gro it is necessary to remove the methanol entirely an to this end a more complicated method must b employed. We therefore propose the followin method. 1 ml. $Si(OCH_3)_4$ is mixed with 10–20 m water, when there appears a slight turbidity. Th solution is centrifuged until it becomes clear an then poured into tubes or other suitable vessel The solution becomes a clear gel when the vesse have been left standing at room temperature for son days or are kept warm in an autoclave in the usu way. Water is poured over the gel, and the methan diffuses into the water and is thus removed. Th water is replaced by a suitable nutrient solution which buffer substances may be added to give th gel a suitable *p*H. The tubes must be kept at temperature high enough to prevent the growth bacteria. When the gel has absorbed the nutrie substances for some time, the liquid above the su face of the gel is poured out, the tubes are aut claved in the usual way, and are then ready for us

The silica gels are more apt to dry up than aga agar, so they ought to be kept in moist air, f example, in a closed jar with some water in th bottom.

The gels have been tested by cultivation of *Ba vulgatus*, *Leuconostoc mesenteroides* and *Schizosacchar myces* Pombe, and in all cases the results were pos tive. Investigations concerning the applicability f bacteriological purposes of silicic acid gels from th methyl ester will be continued by Dr. H. Laurell.

We wish to thank Profs. The Svedberg and Ar Tiselius for the provision of laboratory facilities, well as Dr. H. Laurell for advice. The silico-ester w kindly placed at our disposal by the Uddeho Company (Skoghallsverken), Sweden.

Enamel Cuticle (Nasmyth's Membrane) and Tartar Deposition in the Ferret

A form of parodontal disease has been previous described, in which the initial lesion of the gum w caused by the impingement and eventual penetrati of salivary calculus[1,2]. Both tartar deposition a gingival disease were prevented by including in t diet short lengths of bone with small amounts muscle, tendon and periosteum left *in situ*. The latt attachments fed separately had no prophylactic i fluence, and their importance lay in their providi the main inducement to gnawing of the bone by t animals. The tartar-preventing action of bon gnawing was largely due to the mechanical friction the hard bone against the tooth surfaces, and its cur tive effect on established parodontal lesions was al demonstrated.

While the precise cause of these calcareous acc tions is still undetermined, a series of recent observ tions has led me to believe that the enamel cutic—

Nasmyth's membrane) plays an important part in tartar formation. First, in the relatively young ferret this cuticle covers the whole part of the tooth exposed to the mouth. As the animal grows older, an increasing amount of the cuticle becomes worn off during mastication, the parts of the teeth first and most affected being those which occlude on biting. The more sheltered areas, such as the upper buccal or lower lingual grooves between the carnassial tooth cusps, remain comparatively free from masticatory friction in the absence of access to dietary bone. Even when pieces of bone (plus attachments) do orm part of the ferret's diet, the cuticle in these ntercuspal grooves may retain much of its original hickness for some considerable time. It follows, then, hat at any given time subsequent to complete erupion and full function of the teeth, the amount of namel cuticle on any given area of a tooth depends not only upon the degree of friction exerted by occlusal and masticating stresses, but also upon the anatomical form of the tooth crown. In the ferret he number of sheltered intercuspal grooves is greatest in the molar and upper fourth premolar and least in the incisor teeth, so that, given the same masticatory friction, the latter lose their enamel cuticle at a proportionately faster rate; the difference is, however, to some extent reduced by the fact hat the carnassial teeth bear the brunt of masticaion, especially when bone is gnawed.

Secondly, as described previously, dental calculus first appears in the upper jaw of the ferret in the groove between the buccal cusps of the fourth premolar adjacent to the opening of the parotid duct, and in the occlusal depressions of the somewhat udimentary first molar near the opening of the infraorbital salivary duct. In the lower jaw, calculus is irst laid down in the lingual groove between the first molar cusps adjacent to the orifice of the retroingual gland; in the ferret the latter takes the place of submaxillary and sublingual glands. In other words, the mouths of the salivary ducts are close to hose particular areas of the denture in which the namel cuticle is relatively persistent and which in urn show the first and heaviest accretions of tartar.

Thirdly, microscopic preparations of teeth and parodontal tissues clearly demonstrate the very firm adherence of the organic constituents of tartar to he enamel cuticle, even after such drastic treatment as decalcification in 2 per cent nitric or hydrochloric acid, dehydration in alcohol and ether, celloidin and/or paraffin impregnation, and sectioning on the microome. The implication is that some association exists between the organic constituents of tartar and enamel uticle. Moreover, there is evidence to indicate that, in ferrets given bone to gnaw, not only are they free from tartar and parodontal disease, but also *in time* he enamel cuticle is itself largely removed by friction and, on subsequent withdrawal of the dietary bone, the teeth still remain free from all but a trace of tartar in the most sheltered grooves distant from the um margin.

Finally, under certain conditions, calcium-containing material is laid down *in vitro* on pieces of enamel uticle, removed by acid from ferret or human teeth, n incubation in human saliva.

It seemed possible that the foregoing findings might be something more than coincidental and, indeed, hat presence of the enamel cuticle might be a prerequisite for the deposition of dental calculus. With the purpose of determining whether or not the cuticle is indispensable to the initial formation of tartar in ferrets, a series of experiments is now in progress in which the teeth of animals fed on bone-free diets are being submitted to various procedures designed to remove or destroy the enamel cuticle.

The results will be reported in due course, but already some evidence has been obtained in support of this new approach to an old problem.

Conditioned Excitors and Human Sense Organs

ABOUT ten years ago, Alexey Bogoslavsky and Krikor Kekcheyev in Moscow and Alexander Dolin in Leningrad, working independently, demonstrated experimentally that the sensitivity of the human sense organs may be considerably modified under the influence of an indifferent factor, for example, the weak beat of a metronome, if it is accompanied several times by the influence of an active excitor. It was found that the latter, acting on an appropriate sense organ (for example, a sweet substance on the taste organ, or an odorous substance on the sense of smell), simultaneously changed the sensitivity of the entire sensory sphere of the brain. As in other conditioned reflexes, already studied, in which the excited organs were the salivary glands or definite groups of muscles, so in the case of our sensory conditioned reflexes, one rule must be observed: the formerly indifferent, or, as Pavlov called it, the conditioned excitor must be 'reinforced' several days in succession by the action of an excitor which by itself always produces the desired effect (unconditioned excitor).

The Institute of Psychology in Moscow has in recent months conducted a series of experiments in which the conditioned excitor was not a physical agent, but a phrase or sentence, the meaning of which bore no relation to the experiment itself. A passage is read aloud to the subject and when a given phrase is reached his face is rubbed with a cold wet towel. This was done several days in succession, after which measurements of the sensitivity of the eye, or more exactly, of its powers of night vision, revealed a marked enhancement of sensitivity after the phrase constituting the 'conditioned excitor'—and only after that particular phrase—had been read (Dubinskaya). This demonstrated that conditioned sensory reflexes may be formed not only by physical or chemical excitors (Pavlov's first signal system), but also by words and sequences of words (Pavlov's secondary signal system).

In another series of experiments, which is inherently connected with the one just described, the sensitivity of sight and hearing was modified not by the influence of physical excitors themselves (light, sound, cold, mechanical action, etc.), but only by the idea of the corresponding sensations. The changes in one direction or the other were well marked and lasted for about half an hour. The idea of the bright light of automobile headlights invariably enhanced sensitivity of hearing (this effect was also produced by the direct action of light on the eye), and the idea of the noise of a motor, just as the noise itself, always resulted in a marked diminution of sensitivity of night vision. Similar effects are produced by the ideas of sweet and bitter. The idea of the sensation always produced a change, and invariably in the direction which would have resulted from the action of the excitor itself. Emotionally pleasant ideas invariably enhanced the sensitivity of all the sense organs. The idea of weak excitors produced the same effect as the weak excitors themselves. The opposite effect was produced by the idea of strong excitors, for example, of very sour substances or of uncomfortably hot water.

It has been demonstrated in my laboratory that sensitivity to red light increases after action on the eye of its complement green light, and vice versa, although in a lesser degree. This is likewise true of yellow light and its complement, blue light (Schwarz). We now find that the idea of red or yellow light increases the sensitivity of the eye to its complement (green or yellow light), but that the idea of the latter does not have the same effect.

The researches here briefly described transcend the bounds of physiological optics and are of great value for our understanding and quantitative evaluation of certain aspects of the influence of the mind on the physical state in man, and, in particular, on the functional state of the sense organs.

Demonstration of Mitosis in Animal Cells

In a recent communication, Lloyd[1] raises the subject of the teaching of mitosis to zoology students. The materials which he recommends are the developing eggs of various species of nematode worms, and his method is a smear technique.

Slides of maturing and cleaving nematode eggs are also used extensively in the United States and in Canada for teaching mitosis to zoology students; and indeed nowadays it is probably correct to say that the practice is general, except in so far as it has been superseded by the use of slides of cleaving teleost eggs. The nematode used is *Ascaris equorum* Goeze (*A. megalocephala* Cloquet), the horse-worm, which is always readily available and has the advantage of possessing only a small number of chromosomes. The slides are prepared not by a smear technique, which might prove to be considerably easier, but by sectioning the uterus after the fixation of that organ, or of the whole worm, by one of the drastic methods normal for nematodes. Before embedding, the uterus is sometimes bent backwards and forwards upon itself so that each final slide contains numerous sections from several different levels and shows many different stages of mitosis. For a zoologist, these sections of *Ascaris* are in every way superior to those of root tips, and they are as suitable for first-year classes as for advanced students.

However, as an alternative which is considered by some to be even better, whitefish eggs in early stages of cleavage are now being used increasingly (whitefish is a salmonid species, *Coregonus clupeiformis* Mitchill, common in the Great Lakes). Although these eggs are not so readily available, they are easy to prepare in that fixation is simple and sectioning is unnecessary; slides are being marketed in increasing numbers by the large American biologic supply houses which had previously concentrate almost exclusively on the eggs of *Ascaris*.

Late Flowering of Horse-Chestnut

While passing through Paris recently en route t and from Switzerland, I noticed that a number o horse-chestnuts in the streets were still in flower—quite a number on September 11, and a few sti on October 4.

On these dates, perhaps a third of the trees showe foliage normal for the time of year. On the remainde all or most of the leaves were already withered an brown. I understand that this was due to a sever frost, followed by very dry weather in the sprin Of these prematurely withered trees, a considerab proportion showed a few branches or shoots wit normal leaves—indeed, greener than those on th trees which had not been damaged by the frost and a fair number of these green shoots carrie flowers. The same phenomenon, but to a less extent, was noted among horse-chestnut trees i western Switzerland in late September.

It would seem that the premature damage to th foliage had stimulated the production of new shoot from buds that would normally have developed nex spring, some of which managed to flower as well as t produce new leaves. The phenomenon would thu appear to be very similar to the new growth of leave and sometimes of flowers observed in various tree in London after being wholly or largely defoliate by bomb-blast[1]. However, the lateness of blosso must, I think, be exceptional.

Lantern Slides of Line Drawings

The following simple method of making lanter slides of line drawings may be of interest. Whe the diagrams are not already available in printe form, they are drawn in white chalk on a blackboar and photographed directly. The photographic nega tive so obtained is mounted and bound as a lante slide, the resulting projection on a screen being black line drawing on a white background.

As compared with the more usual method of dra ing the diagram in Indian ink, photographing it, ar finally printing the slide from the negative, the savi in time and materials is considerable.

In order to produce the best results by our metho the blackboard should be well cleaned, a chisel-en cut on the chalk, and the negative should be slight under-exposed to minimize traces of backgroun We have found the method suitable for reproduci diagrams of apparatus and mathematical formul It should be equally suitable for biological drawing

Sir Lawrence Bragg, Cavendish professor of experimental physics, University of Cambridge.

Dr. Harold Jeffreys, reader in geophysics, University of Cambridge.

Paul Karrer, professor of experimental chemistry, University of Zurich.

Prof. The Svedberg, professor of physical chemistry, University of Uppsala.

Sir Geoffrey Taylor, Yarrow research professor of the Royal Society.

Medal Awards:

Henry Draper Medal for 1945 to Paul W. Merrill, astronomer, Mt. Wilson Observatory (Carnegie Institution), Pasadena, California, for his many important contributions to astronomical physics, in particular those relating to his researches in stellar spectroscopy.

J. Lawrence Smith Medal (No. 3) to Stuart H. Perry, Adrian, Michigan, for his original investigations of meteoric bodies.

Marcellus Hartley (Public Welfare) Medal to Vannevar Bush in recognition of his outstanding service in bringing to bear the scientific and engineering talent of the United States upon problems of research connected with the war effort.

Daniel Giraud Elliot Medals:

1941. Th. Dobzhansky, for "Genetics and the Origin of Species" (second edition).

1942. Sir D'Arcy Thompson (The University, St. Andrews, Scotland), for "On Growth and Form" (revised and enlarged, 1942).

1943. Karl Spencer Lashley, for "Studies of Cerebral Function in Learning" (*J. Comp. Neurol.*, **79**, 431; 1943).

Mary Clark Thompson Medal to Thomas Wayland Vaughan, in recognition of his outstanding achievement in his ingenious co-ordination of observations and generalizations made in, and bearing on, the fields of stratigraphic geology and palæontology.

The fifth John J. Carty Medal and Award was presented to William Frederick Durand, "in his profession a versatile and creative Engineer; among his colleagues a wise and friendly Counselor; before his students a kindly and inspiring Teacher; to the Nation an able and devoted Servant".

Awards to the National Academy of Sciences and National Research Council:

The American Pharmaceutical Manufacturers' Association Award of Distinction was presented to the National Research Council in recognition of its fundamental contributions to public health in the field of the medical sciences and also in recognition of its essential services to the United States during the First and Second World Wars.

Lord and Taylor Annual American Design Award for 1945 to the National Academy of Sciences in recognition of the outstanding achievements of the men of science in the prosecution of the War and for the furtherance of research for national security.

RECENT INVESTIGATIONS ON THE GROWTH OF BONE

By PROF. P. LACROIX
Institute of Anatomy, University of Louvain

ANY condition in which bone grows or disappears seems bound to involve some of the mechanisms of normal bone growth. Therefore it was felt that, in the long run, the best way to approach some of the problems of surgical bone pathology would be to deal first with normal development, and to submit the whole question to a new inquiry in the light of recent embryological advances.

The first results of this study are now being published[1] and will be briefly summarized here.

(1) In rabbits, the distal growth cartilage of the radius and the growth cartilage of the rib were cut off by two transverse and parallel sections. Their peripheral region was then entirely taken away by four sections at right angles. The disk-shaped growth zone was thus reduced to a small cube consisting exclusively of cartilaginous tissue without any remnant of the ossification groove (Ranvier's "encoche d'ossification"). This piece was grafted into the brain or under the kidney capsule or into the medullary cavity of the tibia in other rabbits. When recovered, it was found to have produced a large quantity of endochondral trabeculæ which were being resorbed and replaced by hæmopoietic marrow. All around the cartilage, cells which seemed to be ordinary fibroblasts had gathered. Some of these cells had taken part in the formation of a thin bony lamella surrounding and flanking the growing cartilage. The formation of this bony ring is a typical example of an induction phenomenon.

Now this observation led to the reconsideration of the structure of the growing long bones, and it was found—however surprising it may seem that such an obvious detail could have been overlooked thus far—that the ossification groove contains a perichondrial ring identical with that of the grafting experiments. The formation of this ring was traced back as follows : in its earliest stage the diaphysis is a continuous bony tube, but after a while its extremity is cut off from the rest of the bone by osteoclasts and becomes the perichondrial ring of the ossification groove ; this change of structure is brought about by the endochondrial tabeculæ beginning to take part in the constitution of the diaphyseal extremities.

From these facts it was inferred that the formation of the normal perichondrial ring and of the earliest form of the diaphysis is the result of inductive activity depending directly or indirectly on the growing cartilage.

(2) Yet another instance of an induction phenomenon in bone growth is provided by the following experiments. A rod of hyaline cartilage was taken from the rib of a rabbit and put into the upper extremity of the tibia of another young rabbit in such a manner that it pierced the centre of its proximal growth cartilage. The latter, in spite of its having been wounded, went on proliferating and a close contact was established between the grafted cartilage and the growth cartilage. After a few weeks the grafted cartilage was the seat of a typical endochondrial ossification. Since the serial sections proved that no cells of the host cartilage had invaded the graft, the phenomenon was to be considered as one of assimilatory induction.

(3) The two previous groups of experiments a clear-cut evidence of the part played by inductio at a much later stage than one would ever hav thought. They point strongly toward the existenc in the growing cartilage of an organizer. The questio has been pushed another step forward by the following crucial experiments.

An alcoholic extract has been prepared from th cartilaginous epiphyses of the long bones of newl born rabbits and injected into the thigh muscles other rabbits. Forty-one days afterwards, a larg osteoma was found in the thigh. Its histologic examination revealed the presence of all the structur which may be analysed in a growing long bone growth cartilage with its characteristic row arrang ment and partially surrounded by a perichondri ring of the ossification groove, circular or triangul diaphysis enveloped by a periosteum and containin a functional hæmopoietic marrow.

Thus not only the endochondrial ossification bu even the organization of the diaphysis seem to b under the influence of a substance or a group o substances which I suggest calling *osteogenin*.

According to the view put forward at the beginnin of this article, evidence should now be sough of the intervention of such a factor in variou pathological and surgical conditions (periosteal an medullary osteogenesis, formation of a fracture callu evolution of a bone graft, etc.). Further research wi then have to show whether the possibility of promoting osteogenesis at will is really within easy reach.

SCIENTIFIC AFFAIRS IN EUROPE

FROM time to time news is being received o scientific men and institutions on the Continen of Europe, who have been cut off from Great Britai for some five years. A note referring to some Belgia biologists and Belgian biological publications, base on material provided by Dr. Julian Huxley, appeare in *Nature* of August 11, p. 166. Dr. John W. Well contributed an article on French and German geographical and geological institutes to *Nature* August 25, p. 243. Dr. F. W. Sansome has referre to correspondence with some Danish men of scienc (*Nature*, September 1, p. 263). Now Dr. Huxley ha put at our disposal two letters received by him fro Dr. N. Tinbergen, of Leyden, and Dr. A. Buzzat Traverso, of Verbania, Pallanza, Italy, the substanc of which is printed below.

Throughout all these communications, the intens desire to re-open relations with scientific men i Great Britain is apparent, and it is to be hoped th British men of science will, as soon as condition permit, get into touch with correspondents in th liberated countries and exchange reprints with then in the interests of international relations.

From Dr. Tinbergen :

The situation in the Netherlands is still more less chaotic. We have great admiration for the sw and efficient help by the 'food flying squads' th have brought immediate relief to our people at a instant when thousands were dying of starvatio We owe an enormous debt of gratitude to the inst gators and organizers of that huge enterprise. Re unger is over now, but the after-effect, bodily and moral and spiritual, of the German terror and hunger ombined is still evident. . . .

Scientific work, which was little affected in the rst year of occupation, has practically come to a andstill in the last year. In 1942 we had a great ash with the Germans, who wanted to nazify the niversity of Leyden; we did not 'surrender' and ook our leave; as a reprisal we were put into an nternment camp as hostages, and spent two years here. They did not shoot us, however, and all but ne of us have safely returned. That one was Prof. 'elders, who died in a German concentration camp. n Utrecht, Jordan has died.

I want to renew and intensify the contact and o-operation with British students of behaviour, and am sure most of my Dutch colleagues in the field of nimal psychology are of the same opinion: we all ave a great longing for international interchange of leas. I do not intend to cut off all relations with erman scientific men. But first I must not see them or a long time, so as to overcome the psychological version resulting from the incredible German terror ve underwent; and secondly I want only to renew ontact, eventually, with those investigators that personally know as honest and reliable men, such s Rensch, von Frisch, Stresemann, Lorenz and I hope) Laven.

As soon as it is permitted, I will send you the ublications that have appeared in my department etween 1939 and 1942, the year of the clash with he Germans, when I stopped all publishing. The ther universities did not have such a formal clash, hough all of them were languishing. Much of my wn recent work has been centred on "das angeborene uslosende Schema" ('releasing mechanism'); field vork on *Satyrus semele*, published in *Z. f. Tierpsychologie*; laboratory work with the three-spined stickleback, an excellent object (most of this work still unpublished); laboratory work with a number of ichlid fishes (unpublished); and field work with he herring gull (only short papers on fragments f the work). Continuation of this last piece of vork will be impossible for some years, to my great egret, as the dunes are 'peppered' with land nines.

Bierens de Haan, after nearly dying of starvation, s all right again; he has written a voluminous book n instincts, and now is writing one on the psychology f the dog. Portielje is all right, and active as ever. Ie wrote an interesting study of the orang-utan. 'erwey had to leave his laboratory in Den Helder, hich in the course of the War was absolutely robbed y the Germans; he was fifteen months among us as a ostage in the same internment camp, as also were rof. Van der Klaauw, and Koningsberger, the trecht botanist, successor of Went. A new star in he sky of animal psychology is A. Kortlandt, a oung fellow, very clever, very original, very 'cormorant-minded'; for years he has lived among the ekkerkerk cormorants, day and night, most of the me in a hide in the nest-trees, where he often tayed for one or more weeks, day and night continuously, receiving his food by a 'téléférique' *Drahtseilbahn*).

Kluyver, the starling man, is all right; he had to ave Wageningen in September 1944, and his house as badly damaged, but he managed to save all the otes of his extensive study on the great tit, and ost of his books, and has recently returned. The overnment Phytopathological Service, where Kluyver was the ornithologist, has been absolutely ruined by the Germans. All records and files have been burned, as well as the library, one of the many instances of the enormous setback caused by the War. Sirks, Hazelhoff, Dijkgraaf (nephew and pupil of Von Frisch), Raven, Krijgsman, my brother L. Tinbergen, Ihle, De Beaufort are all right. Ihle very nearly died of starvation. Owing to the very limited possibilities of travelling and writing (no trains; cycling only possible during some hours of the night, to avoid the German slave-hunters), we heard such things mostly too late to help each other. De Burlet, much to our regret, has been co-operating with the Germans. He has fled and nobody knows where he is. Hirsch, who was a German, seems to be in Germany.

You may wonder whether we will have time to resume 'pure' scientific research, now that all kinds of reconstruction work will demand so much of our energy. I am sure that we will succeed in keeping part of our time for research.

From Dr. Buzzati-Traverso:

It has been possible for myself and some of my students to carry out a good deal of work (largely published in Italy) on the population genetics of various European species of *Drosophila*, and on induced chromosome mutations. The work was planned jointly with Timoféeff-Ressovsky, in whose Institute in Berlin I worked for five months in 1942. (The last news I had of Timoféeff-Ressovsky was from Hans Bauer in November 1944, to say that he was still working in Berlin. Bauer was then working near Tübingen, where the whole Kaiser Wilhelm Institut für Biologie had been transferred, after being slightly damaged in the early bombing of Berlin.) In Italy the work was done at the University of Pavia. As soon as possible after the Italian armistice, I transported everything I could from Pavia to the Istituto Italiano di Idrobiologia at Pallanza, and thus was saved from destruction a collection of more than two hundred stock cultures of *Drosophila*. This, I believe, is the only collection of *Drosophila* stocks surviving in continental Europe outside the U.S.S.R.

The Istituto Italiano di Idrobiologia was founded in 1939. It is a private foundation with two main laboratories, the principal at Pallanza, the other at Varenna on Lake Como. This is a research institute devoted to the study of problems of lake biology and of limnology. The director, Prof. Edgardo Baldi, is interested in problems of freshwater biology which are of significance for more general biological questions; the Institute is largely concerned with problems of the biology of the animals of freshwater basins. During the last couple of years, a number of such questions have been investigated from the point of view of population genetics.

My stay here has shown me that the combination of field work and study with genetics is likely to be fruitful. Accordingly, Dr. Baldi and I have decided to set up a genetics department of the Institute, under my supervision. We have a number of able young men available for work in this field, including Dr. L. Carvalli, a brilliant worker in statistical genetics and biometry. Our financial prospects appear bright.

In 1943, Prof. Baldi organized a symposium, in which about a dozen biologists, palæontologists and geologists took part, on micro-evolution during the Pleistocene. We have also worked out plans for co-operative work in the mountains above Trieste and in the region of Monte Circeo between Rome and

Naples, though the political and military position has so far not permitted their realization.

Italian biology was not good even before the War, and has since become worse owing to the destruction of many university laboratories and libraries. We feel that there is not much to hope for immediately from the academic milieu, because on one hand the new Italian Government is facing much more urgent problems than university re-organization, and on the other hand many professors of biology are wholly out of sympathy with modern ideas in this subject, and unlikely to be removed from their posts. Accordingly, we believe that the only way to improve the level of biological research and to raise a new generation of modern-minded biologists is to have institutes outside the universities which, keeping the closest possible contacts with foreign laboratories, should introduce the methods and the approach which I have had the good fortune to know and to appreciate in the United States, in Britain, and in some German laboratories. We think that for the time being such extra-university institutes might be the Istituto di Idrobiologia, the Stazione Zoologica in Naples, and perhaps the Istituto do Sanità Pubblica in Rome, which includes well-known physicists, such as Edoardo Amandi, who are very much interested in biophysical problems.

The most urgent need for us now is to become acquainted with the scientific production of the Allied Nations during the last five years. We need books and journals concerning genetic, ecological and general biological problems, to make our existing library comprehensive and up to date.

I suppose that in connexion with any new international organization, some kind of committee for international scientific co-operation is likely to be set up.

Dr. Huxley has also added the following postscript containing further information which he has obtained while in Switzerland and France during September.

(1) *German Ornithology*. While in Switzerland, I was given a copy of a letter written on August 1 by Dr. Erwin Stresemann of Berlin, the leading continental ornithologist, to a Swiss colleague:

> The centre of the city has been almost completely destroyed and has become a ghastly heap of rubble. Our museum, however, has not been too badly damaged and we have been doing repair work for some weeks, with a view to opening the collection to the public. Two rooms of the bird department were very badly damaged during an air raid on March 18, 1945, thus unfortunately destroying almost the entire scientific collection of stuffed birds of 1810–88, as it had not been possible to move these from their cases owing to lack of space and means of transport—for there are (or were) 25,000 specimens! I was, however, able to evacuate most of the types to safety, as well as the modern collection of skins and all the books. I have for some time been engaged in bringing these back to their old home and arranging the bird department as it used to be. I am being helped in this work by Mr. Hermann Grote, who has been appointed as my assistant. The important library of the Deutsche Ornithologische Gesellschaft and the stock of unsold journals (*J. Ornithologie, Ornith. Monatsberichte*, etc.) have also been saved.
>
> As we in Berlin are cut off from the world, I still know little about the fate of ornithologists in other parts of Germany. Dr. Oskar Heinroth died of pneumonia on May 31, 1945, consequent upon mar nights spent in an air-raid shelter during the heav raids of March and April—an irreplaceable loss. news of Schuster. Dr. Otto Schnurre visited me short time ago: he is now *kommisarischer* direct of the Berlin City Library. Dr. E. Schütz wro from Danzig last March, when that town was e circled and being attacked by the Russians—wh may his fate have been? Dr. F. Tischler has r mained in East Prussia. There is no news at all the numerous Silesian ornithologists. The bi observatories of Heligoland and Rossitten are pro ably things of the past—for all time. I cannot the present moment say whether I shall ever able to re-start the *J. Ornithologie* and the *Ornit Monatsberichte*; for the time being their resumpti is unthinkable.
>
> That great pioneer in animal psychology, Pro Konrad Lorenz, was last summer reported missi near Vitebsk, probably killed; he was working as doctor in a front-line hospital.
>
> I expect that professional circles abroad will interested to hear how the War and the collapse Germany have affected German ornithology. I da not think that it has disappeared for ever, and long as I am able to do so I will devote all my energi to it, so that it may, at some future time, rise phœni like from its ashes. . . .
>
> P.S.—The ringing records of the bird observatory Rossitten were removed to Central Germany in tim and I expect that they are safe and can be use again in the future.

It may be recalled that Dr. Stresemann gave acti help and encouragement during the War to tw young British prisoner-of-war ornithologists, wh organized groups in their prison camps to study th detailed behaviour of certain bird species. We ma shortly expect the publication of their valuab data, obtained in circumstances that must unprecedented.

(2) *German Genetics*. Through Prof. Boris Ephrus of Paris I heard the welcome news that Dr. Timoféef Ressovsky, the eminent Berlin geneticist of Russia origin, has made satisfactory arrangements with th Russian authorities to continue his work in th U.S.S.R., and has already left Berlin with most the staff and equipment of his Institute.

(3) *General Biology in Germany*. Inquiries i zoological circles in Switzerland elicited the followi facts concerning German and Austrian biologists.

Hans Baur (Berlin), M. Henze (previously Innsbruck), E. Rotmann (Cologne Vogt) an probably A. Kühn are alive. Von Buddenbrock, th well-known comparative physiologist, was demote (*strafversetzt*) from Halle to Vienna in 1942 becau of his general opposition to Nazi ideas, and wa thence evacuated by the Americans with many oth men of science to the American zone in German where (in late August of this year) he was in gra financial straits and was not allowed to receive send correspondence to foreign countries. The thi volume of his great book on comparative physiolog dealing with hormones, is now in slip proof, and has begun writing the fourth volume. As it is pro ably impossible for him to return to Vienna, it wou seem highly desirable for this eminent and non-Na man of science to be given a post, in Germany elsewhere, as soon as possible.

A. Penners of Vienna was very badly treated the Nazis, and was probably dismissed from his pos

He attempted unsuccessfully to go to Switzerland before the outbreak of the War. His present whereabouts are uncertain. Ries, Wettstein and probably Seidel are dead. K. Henke and E. v. Holst (Göttingen), Paula Hertwig (Berlin), Hans Nachtsheim and Otto Warburg (Berlin-Dahlem) appear to have been alive at the end of the War, but no news of them has since been received. J. Haemmerling moved from Berlin-Dahlem to the Institut für Seenforschung on the Lake of Constance, but nothing has recently been heard from him.

(4) *Hungary and Czechoslovakia.* I have just heard through the Red Cross that Dr. Alexander Wolsky, he zoologist at the Biological Research Station at Tihany, is alive and well (and also his family) and hat the Research Station is undamaged.

I have also heard that Prof. Jan Belehradek, one-ime professor of zoology and later rector of the Karlovy University of Prague, is well, though he was imprisoned in a concentration camp for a considerable period.

Those who knew Dr. Wolsky and Prof. Belehradek when they were doing research in London in the '30's will be especially glad to hear this good news of hem.

RESEARCH IN THE U.S.S.R. ON THE PHYSIOLOGY OF VISION

THE physiology of vision has always held a peculiar fascination for the physiological theorist, but recently the urgency of immediate practical problems, brought to a focus by the War, has led to a enewed and more direct approach both in this country and abroad. Recent Russian work in this field is published in *Problemy Physiologitchesky Optiky*, 2 (Moscow, 1944), which contains sixteen papers from eleven different laboratories. The papers are in Russian, but a generous English abstract of each is given.

Dealing first with work of immediate practical application, V. G. Samsonova has studied the influence of size of image, central brightness, ratio of central to peripheral brightness on the visual discrimination ime, and has constructed nomograms from which optimum conditions of lighting for factories, etc., can be computed. O. P. Kholmskaya has measured he visibility of traffic lights against a black screen of varying size. The minimum size of screen for optimum visibility is one which subtends an angle of 12′; when the subtended angle is less than 3′ visibility is worse than with no screen at all. C. I. Krol finds that with several stimuli in the visual field and the total area of stimulation kept constant, the ensitivity of the eye varies inversely as the number of stimuli. S. V. Kravkov records changes in visual acuity resulting from auditory stimulation, and O. A. Dobriakova finds that various extraneous stimuli increase the critical frequency for flicker at the red end of the spectrum and decrease it at the blue end; here is a peak of increase in the orange-red and of decrease in the blue-green and an intermediate neutral zone in the yellow.

Turning to more fundamental researches, N. I. Pinegin has made a detailed quantitative study of he absolute sensitivity of the eye in the ultra-violet; at 365μ the eye is 11,000 times less sensitive than at 546μ, and the lower limit of vision is 302μ (Goodeve, Lythgoe and Schneider recently placed the lower limit at 309μ). Evidence is provided that the effects were due to direct retinal stimulation at this wavelength and were not the result of fluorescence in the eye media. M. N. Livanov has studied action potentials in the visual cortex and lateral geniculate body with the electroencephalograph. P. I. Spielberg has recorded action currents from the human eye by means of special electrodes applied to the eyeball; the method is fairly simple and may prove useful in ophthalmic practice. A. I. Bogoslovsky has investigated the response of the human eye to electrical excitation. Bogoslovsky has also found that in dark adaptation, while the excitability of the retina increases, that of the visual cortex decreases and the two seem to be reciprocally related.

When a coloured object is viewed at increasing distances, a point is reached (when the subtended angle is 10–20′) at which the colour changes in a characteristic fashion. B. N. Kompaneisky has studied these colour changes and concludes that the results can best be interpreted on a classical trichromatic theory of colour vision. The method also provides a sensitive test of colour vision; there are some variations even among normal individuals, and colour defectives are readily identified.

FORTHCOMING EVENTS

(*Meeting marked with an asterisk * is open to the public*)

THE DISCOVERY OF X-RAYS

50TH ANNIVERSARY COMMEMORATION PROGRAMME

Medical Meeting

Saturday, November 10

At the Institution of Electrical Engineers, at 2 p.m.

Scientific Meeting

Saturday, November 10

At the Royal Institution, at 10 a.m.

Historical Reviews

Saturday, November 10

At the Institution of Electrical Engineers, at 3.30 p.m.

Saturday, November 10

BIOCHEMICAL SOCIETY (at the London School of Hygiene, Keppel Street, London, W.C.1), at 11.30 a.m.—Discussion on "The Chemical Basis of Cell Structure and Function" (to be opened by Dr. J. F. Danielli and others)

IRON AND STEEL INSTITUTE (joint meeting with the SCOTTISH BRANCH OF THE INSTITUTE OF BRITISH FOUNDRYMEN) (at the Royal Technical College, George Street, Glasgow), at 3 p.m.—Mr. Basil Gray: "The German Steel Foundry Industry".

Monday, November 12

ROYAL GEOGRAPHICAL SOCIETY (at Kensington Gore, South Kensington, London, S.W.7), at 5.30 p.m.—Prof. H. W. Ahlmann: "Summary of Glaciological Researches, 1918–1940".

Tuesday, November 13

CHADWICK PUBLIC LECTURE (at the Royal Sanitary Institute, 90 Buckingham Palace Road, London, S.W.1), at 2.30 p.m.—Mr. F. C. Vokes: "The Modern System of Sewage Disposal and the Methods and Materials Employed" (Bossom Gift Lecture)*.

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 5.15 p.m.—Dr. A. Müller: "50th Anniversary of the Discovery of X-Rays", (ii) "After the Discovery of X-Rays".

ROYAL SOCIETY OF MEDICINE (at 1 Wimpole Street, London, W.1), at 5.30 p.m.—Discussion on "Forward Psychiatry in the Army" (to be opened by Lieut.-Colonel H. A. Palmer, Major C. Kenton, Lieut.-Colonel H. B. Craigie and Lieut.-Colonel T. F. Main).

BRITISH ASSOCIATION OF CHEMISTS, NORTHERN SECTION (in the Chemistry Lecture Theatre, King's College, Newcastle-upon-Tyne), at 7 p.m.—Mr. R. Booth: "The Development and Properties of Safety Glass".

Wednesday, November 14

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Mr. A. C. Hartley: "Operation PLUTO".

INSTITUTE OF PETROLEUM (at 26 Portland Place, London, W.1), at 5.30 p.m.—Flight-Lieut. E. Mikolajewski: "Investigation of Piston Ring Sticking in High Duty Aero Engines".

INSTITUTION OF ELECTRICAL ENGINEERS, TRANSMISSION SECTION (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. W. J. Nicholls: "Recent Progress in the Design of the High-Voltage Overhead Lines of the British Grid System".

BRITISH INSTITUTION OF RADIO ENGINEERS (at the Neville Hall, Westgate Road, Newcastle-upon-Tyne), at 6 p.m.—Mr. S. G. Button: "U.H.F. Aerial Systems".

British Institution of Radio Engineers (at the Institution of Structural Engineers, 11 Upper Belgrave Street, London, S.W.1), at 6.15 p m.—Discussion on the Radio Industry Council Report on "Post-War European Broadcasting" (to be opened by Mr. R G. Clark).

Thursday, November 15

London Mathematical Society (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W 1), at 3 p.m.—Annual General Meeting. Prof. L. J. Mordell, F R S.. "Thoughts on Number-Theory" (Presidential Address).

Chemical Society (in the Muspratt Lecture Theatre, The University, Liverpool), at 4 p.m.—Mr R. P. Bell, F.R.S : "The Structure of the Boron Hydrides and Related Compounds".

Royal Institution (at 21 Albemarle Street, London, W 1), at 5 15 p.m.—Prof. James Gray, F.R.S.: "The Anatomy and Functions of the Brain in Lower Vertebrates", (iii). "Birds".

Institution of Electrical Engineers (at Savoy Place, Victoria Embankment, London, W C 2), at 5.30 p.m.—Mr R. Davis · "High-Voltage Research at the National Physical Laboratory" (Parsons Memorial Lecture).

Royal Society of Tropical Medicine and Hygiene (in the Bacteriological Laboratory of the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 8 p m.—Laboratory Meeting.

Friday, November 16

Royal Institution (at 21 Albemarle Street, London, W 1), at 5.15 p m.—Dr. A. O. Rankine, F.R.S.: "The Dispersal of Fog on Airfields".

Chemical Society (joint meeting with the **University Chemical Society**) (in the Chemistry Lecture Theatre, The University, Sheffield), at 5 30 p.m.—Prof. I M Heilbron, F.R S . "Our War Against Insect Pests".

Institution of Mechanical Engineers (at Storey's Gate, St. James's Park, London, S.W 1), at 5 30 p m —Sir Edward Appleton, K C.B., F.R S.. "The Scientist in War Time" (Thirty-second Thomas Hawksley Lecture)

Chemical Society (in the Chemistry Lecture Theatre, The University, Manchester), at 6 p m.—Original Papers.

Royal Institute of Chemistry (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 6 p m —Mr. W. Gordon Carey: "Water and Public Health" (Twenty-eighth Streatfeild Memorial Lecture).

British Institution of Radio Engineers (in the Physics Lecture Theatre, University College, Southampton), at 6.15 p.m —Dr Hilary Moss: "Engineering Methods in the Design of the Cathode Ray Tube".

Society of Chemical Industry, Plastics Group (joint meeting of the **Birmingham and Midlands Sections** of the **Society** and the **Royal Institute of Chemistry**) (in the English Theatre, The University, Edmund Street, Birmingham), at 6.30 p.m —Dr. J. C. Swallow: "Polythene".

Chemical Society (at the Royal Technical College, Glasgow), at 7.15 p.m.—Prof J. M. Gulland, F.R.S : "Polynucleotides and Nucleoproteins".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned·

Laboratory Steward for Chemistry, a **Laboratory Steward for Physics**, and **Laboratory Assistants**—The Principal, Acton Technical College, High Street, Acton, London, W.3 (November 14).

Routine Chemist for Trinidad, British West Indies, by a firm producing and refining petroleum products—The Ministry of Labour and National Service, Appointments Department, Technical and Scientific Register, Room 670, York House, Kingsway, London, W C.2, quoting F.5055.XA (November 16)

Head of the Engineering Department of the Newport Technical College—The Director of Education, Education Offices, Charles Street, Newport (November 16).

Graduate Teacher to take classes in **Physics** and **Mathematics** up to Higher School Certificate standard, or Engineering Subjects—The Principal, Stroud and District Technical College, Stroud, Glos. (November 17)

Special Salt Development Officer to the Government of Bengal—The Ministry of Labour and National Service, Appointments Department, Technical and Scientific Register, Room 670, York House, Kingsway, London, W C 2, quoting E 2057 A (November 24).

Assistant Lecturer in Preparing, Combing and Spinning in the Bradford Technical College—The Director of Education, Town Hall, Bradford (November 24).

Lecturer in Geography—The Registrar, The University, Manchester 13 (November 25).

Senior Assistant in Engineering Department, and a **Lecturer in General Engineering Subjects**, in the Burnley Municipal College—The Director of Education, Education Offices, Burnley (November 26)

Drilling Engineer for service in the Sudan, on the operation of Drilling Plant, and well digging under the direction of the Sudan Government Geologist—The Ministry of Labour and National Service, Appointments Department, Technical and Scientific Register, Room 670, York House, Kingsway, London, W C.2, quoting C 2855.A (November 26).

Assistant Examiner of Questioned Documents, Government of India—The Ministry of Labour and National Service, Appointments Department, Technical and Scientific Register, Room 670, York House, Kingsway, London, W.C.2, quoting F 5101 A (November 26).

Engineering Assistant (completed A M I C.E. examination), a **Junior Engineering Assistant** (completed A.M I C E examination) and a **Junior Engineering Assistant** (not completed A.M I.C.E examination), on the staff of the Engineer of the River Ouse Catchment Board—The Clerk of the Board, 7 Langcliffe Avenue, Harrogat (November 28).

Director of Museums—The Town Clerk, Municipal Buildings Dale Street, Liverpool 2, endorsed 'Director of Museums' (Novembe 30)

Civil, Mechanical and Electrical Engineers in Malaya an Hong Kong—Civil Engineers (Ref. E.2097 A) should have had experience of construction of railways or open-line maintenance, alternatively, they should have had experience of construction and maintenance of roads, or of Urban Water Supply and Draining, or of Irrigation and Land Drainage; Mechanical Engineers (Ref C 2904.A) should have had practical experience of power generation and distribution and manufacture of plant used therein; Electrical Engineers (Ref D.1535.A) should have had training in Telegraph, Telephone and Radi Engineering—The Ministry of Labour and National Service, Appointments Department, Technical and Scientific Register, Room 670, York House, Kingsway, London, W C.2, quoting the appropriat Ref. No. (November 30).

Lecturer in the Department of Naval Architecture—Th Registrar, King's College, Newcastle-upon-Tyne (November 30).

Assistant Registrar in the Medical School—The Registrar, King' College, Newcastle-upon-Tyne (November 30)

Lecturer in the Department of Bacteriology—The Registrar, King's College, Newcastle-upon-Tyne (November 30).

Lecturer in Geography—The Secretary, The University, Edinburgh (November 30)

Assistant Lecturer in Inorganic and Physical Chemistry—The Acting Registrar, Queen Mary College, Mile End Road, London, E.1 (November 30).

Assistant Lecturer in Mechanical Engineering—The Clerk to the Governors, Battersea Polytechnic, Battersea, London, S.W.11 (December 14).

Research Worker in the **Pomology Section** for field experiments, and an **Assistant Mycologist and Bacteriologist** in the Plant Pathology Section—The Secretary, East Malling Research Station, Maidstone, Kent (December 15).

Reader in Zoology and **Head of the Department of Zoology** in the Durham Colleges—The Registrar, University of Durham Office, 46 North Bailey, Durham (December 31)

Professor of Physics, a **Professor of Agriculture**, a **Professor of Agricultural Economics** (who is also Adviser in Agricultura Economics for Wales), and the **Gregynog Chair of Geography and Anthropology**—The Registrar, University College of Wales, Aberystwyth (December 31).

Assistant Lecturer in Mathematics—The Registrar, The University, Sheffield (December 31).

Entomologist, and a **Plant Pathologist**, at the Tobacco Research Station, Trelawney, Southern Rhodesia—The Chairman, Tobacco Research Board, P.O. Box 387, Salisbury, Southern Rhodesia (December 31).

Assistant Lecturer (Grade III) **in the Department of Metallurgy**—The Registrar, The University, Liverpool (January 1)

Principal—The Secretary, King's College of Household and Socia Science, c/o University College, Leicester (January 1).

Sub-Librarian—The Secretary, The University, Aberdeen (February 15).

Lecturer in Physiology—The Registrar, The University, Leeds, 2 (February 16)

Secretary—The Secretary, Executive Council of the Imperia Agricultural Bureaux, 2 Queen Anne's Gate Buildings, Dartmout Street, London, S.W.1 (April 7).

Lecturer in the Department of Mechanical Engineering—The Principal, Birmingham Central Technical College, Suffolk Street Birmingham 1.

Teacher (full-time) **of Engineering Subjects**—The Principal Workington Technical College, Workington, Cumberland.

Teacher (Graduate, or equivalent) with industrial experience in Engineering and qualified to teach **Electrical Engineering** to th Ordinary National Certificate stage—The Principal, Technical College, Stretford, Lancs.

Lecturer (full-time) **in the Department of Mathematics**—Th Secretary, Northampton Polytechnic, St. John Street, London, E.C.1.

Lecturer (full-time) highly qualified in **Mathematics**, for advance Engineering Courses preparing for Final B.Sc. and Higher Nationa Certificate—The Organizer of Further Education in Rugby, College o Technology and Arts, Eastlands, Rugby.

Laboratory Attendant for Physics Laboratory—The Secretary to the Governors, Royal Holloway College, Englefield Green, Surrey.

Lecturer (full-time) **in Mathematics**—The Principal, College o Technology and Commerce, Leicester.

Assistant (with a special knowledge of Physical Chemistry) **in th Department of Chemistry**—The Secretary, The University, Aberdeen.

Laboratory Steward in the Department of Botany—The Hea of the Department of Botany, University College, Hull

Graduate Physical Chemist with an aptitude for scientific researc to work on the permeability of packaging materials and packages t gases, and a **Graduate Physical Chemist** with an aptitude fo scientific research to work on the physical and chemical propertie of adhesives used in the packaging and printing industries—Th Director of Research, Printing and Allied Trades Research Association Charterhouse Chambers, Charterhouse Square, London, E C 1.

Senior Physicist to organize and collate investigations on th physical properties of leather—The Director, British Leather Manufacturers' Research Association, 1–6 Nelson Square, London, S.E 1.

TEAM WORK IN SCIENCE

IN the accounts of scientific effort during the War on which the veil of secrecy has now been lifted, one common feature stands out on even the most casual reading. Whether we look at the efforts which went to the development of the atomic bomb, of radar, of 'Pluto', 'Fido', and British flame weapons, or in a vastly different field, of penicillin, the extent to which the achievements depend on team work is unmistakable. Sir Cecil Weir was at pains recently to emphasize the way in which in 1942 the Ministry of Supply brought together potential manufacturers of penicillin and interested men of science, and the fact that production was under way or about to commence in twelve factories run by eight firms was the direct outcome of the team work thus engendered. As a particular instance is the help given by experts of the Medical Research Council, and especially Dr. R. I. N. Greaves, of the Serum Drying Unit, Cambridge, in the design of the freeze-drying plant of the Glaxo penicillin plant at Greenford.

Again, Mr. Geoffrey Lloyd, who was in charge of the Petroleum Warfare Department from its formation in 1940 until the resignation of Mr. Churchill's Government, in reviewing the lessons from petroleum warfare, stressed the immense value of research and development teams, and the advantage, in dealing with a particularly stubborn problem, of getting almost completely separate teams to work from quite different aspects. Research and experiment, while they must be directed towards definite objectives, should proceed on a broad front, and policy control should be elastic. Mr. Geoffrey Lloyd was urging the need for a forward surge over the whole range of creative inquiry and invention for peace purposes, and it would be easy to multiply examples of this need and of the place of team work and co-operation in meeting it.

No field better illustrates this truth than the development of radar, and whether we take the Department of Scientific and Industrial Research's papers released in August by the Ministry of Production, the United States Government account "Radar : a Report on Science at War", or the article "Radar in War and Peace" which Sir Robert Watson-Watt recently contributed to *Nature* (156, 319; Sept. 15, 1945), the extent to which this great scientific achievement depended on a most remarkable integration of pure and applied science is clearly shown. In a statement to a Press conference at the Ministry of Information on August 14, Sir Stafford Cripps attributed to the bringing together of the Air Staff and their scientific advisers, distinguished outside scientific workers with wide contacts and fresh outlook, and the members of the National Physical Laboratory radio team, who had been encouraged by the Radio Research Board in fundamental research going right down to the root of radio problems, the immediate solution of the basic problem of air defence. From the appointment of this committee by Lord Swinton in 1935, considering the great complexity of the subject, progress was rapid, and an official document, cited by Sir Robert

Watson-Watt, describes the formation of this Committee for the Scientific Survey of Air Defence, with the contact between a user Department with a great need, and a Department which had fostered scientific discovery not wholly directed towards specific needs, as one of the most important events in our history.

Sir Robert Watson-Watt is at pains to bring out the way the story illustrates the need for encouraging scientific research in all fields and for making the needs of the State known to those who are engaged in scientific research, though he alone in his account passes over his own important contributions in these early developments. No account brings out more clearly than his own, however, the way in which the development of radar is based on Appleton's classical range measurement on the ionosphere and Breit and Tuve's powerful tool, the radio pulse. The beginnings of radiolocation, Sir Robert points out, lay in the work of those who laboured to understand more of the things that happened in the earth's atmosphere. Its later developments, and much of its technique at all times, were due to those who sought the inner secrets of the structure of matter.

Nor was this all. Sir Robert maintains that the most important thing about the British development of radiolocation is that it happened at the right time, and the essential differences between the British effort and that in other countries is to be found in the intangible factors which assured to us at each stage in development at least an adequate margin of time for meeting the successive crises of the War. Britain was a prominent leader in ionosphere research, and those researches were State-aided and generously and lightly State-controlled, and Sir Robert considers that without the peaceful pursuits of the Radio Research Board in general and of Sir Edward Appleton and his colleagues in ionospheric research in particular, radiolocation would have come too late to have any decisive influence in the War. Further, the Radio Research Board had trained a team of young research workers encouraged to see and explore the whole gap between the Morse key and the loudspeaker, and while turning their vision and imagination generally towards application, taking neither narrow nor short views. Sir Robert again stresses the importance of the spiritual ingredients—wisdom, sound judgment and courage—in the scientific advisers, the scientific workers, and the administrative officers who staked some millions of pounds of public money and revised the air defence system of the country ; but the most significant factor was the unprecedented and unprecedentedly productive interplay between scientific and operational minds, which carried the basic technique from its first defensive application in an early warning system through more actively defensive phases to a wealth of offensive applications which had a decisive effect in every major phase of the War.

This intimate co-operation of scientific and military minds, he suggests, will remain as the real secret weapon in the British armoury. Nowhere else has there been a parallel to the practice followed from the first days of radiolocation research. This fruitful co-operation, moreover, extended to the selection training of personnel to operate and maintain systems, to the evolution and practising of tact methods based on the systems, and to the wl complex of technical, tactical and logistic proble involved in introducing new scientific devices i heavily engaged operational formations.

Even that valuable tradition of constructive del between General and junior scientific officer and the extricable weaving of contributions from operatic officer and scientific worker is not the only lessoi co-operation and team work that radiolocation to teach. Almost equally impressive is Sir Robe picture of the building up into a single team of later and much more numerous recruits, not me the cream of the physical research laboratories of country but also chemists, physiologists, biologi dons and schoolmasters, united by certain b characteristics common to all branches of scie This whole combination of technical objectivity the highest technical skill in one team, coupled w the remarkable organization for rapid production team work on the part of industry to which Stafford Cripps has paid tribute in addressing Council of the Radio Industry, is indeed, as Robert suggests, even more important and signific than the technical devices issuing from it.

Moreover, in this there was the partnership built between the Government establishments, the univ sities and the industrial laboratories, and beyo that the pooling from the time of the Tizard miss in 1940 onward of British and American informat over the whole field of radiolocation. The arran ments made for the interchange of information tween the United States and the British Comm wealth, following on this first pooling of knowle and ideas, were reinforced by the community interest and understanding which at all times li the leading scientific workers in friendly fellowship well as by the intimate contact with operatio needs which the British workers, as Sir Robert sho enjoyed from the start. In sum, the joint effo have led to results which have not only been righ described as the heart of our war effort, but n well prove to hold the key to success in the t of reconstruction.

Equally impressive is the picture of war inve gations carried out by large groups which Prof. C. Lander gave in his Melchett lecture, "Team Work Research". These investigations covered combust work in connexion with gas turbines and jet p pulsion, research and development of a model law predict performances of flame-throwers, and resea and development on petrol burners and their supp and signalling arrangements for fog dispersal on ae dromes. Prof. Lander, moreover, points out that his own experience in peace-time, when he starting the survey of the coal resources of Gr Britain, he had been faced with the problem knitting together the contributions of organic, organic and physical chemists ; of physicists, g logists, zoologists, botanists and palæobotanists ; mining, civil and mechanical engineers ; and of and fuel technologists.

Much of Prof. Lander's lecture was of technical interest, but he was at pains to stress the importance of the task of the team leader in holding the balance between the specialized advices of his team members; and he insisted that such a leader must above all possess that critical sense which is based on a wide experience and broad knowledge of scientific work. A team leader must also possess sufficient knowledge of the various sciences to enable him to follow the reasoning of the individual members of the team. Prof. Lander gave little indication as to how the organization of such a team should be built up, though his whole lecture was a challenge to narrow specialization in technical education. He recognized that the team leader requires breadth of understanding in the human as well as the technical sense, but he did not indicate so clearly as Sir Robert Watson-Watt that the members of the team should themselves possess similar qualities to some extent, particularly a capacity for the self-criticism necessary for realizing the possibility of bias and for generating toleration for the inevitable bias in others. It will be noted, however, that while Prof. Lander recognized that secrecy may be necessary, at any rate for the time, he stressed the great importance of publication, especially publication under the names of the men responsible for the particular pieces of work.

It is against the background of this experience and the lessons it enforces that we have to regard in fact future proposals for the organization of research and development, whether in industry, in the Government service or in the universities themselves. Proposals for the reorganization and recruitment of the scientific civil service, for the expansion of industrial research, and for university development must be considered from the point of view of how far they embody the relevant lessons of this war-time experience of team work and the full and free interchange of knowledge and ideas. These are not, of course, the sole criteria, but no proposals which fail to foster the outlook and the temper of mind in which team work of this kind flourishes best can well be entertained except on the basis of the most powerful and convincing reasons.

The two most impressive features of this particular aspect of radiolocation team work in development and research which are stressed not only by Sir Robert Watson-Watt, but also in the British and the United States official accounts, are indeed in regard to the interchange of information and the treatment of scientific staff. No one who has followed at all closely reports or statements on scientific and industrial research, such as that of Nuffield College, during the last two years or so, or studied the recent report of the Barlow Committee on Scientific Staff or, on the American side, those of Dr. Vannevar Bush and his advisory committees, can fail to note how well in line with precept and principles stressed in those documents practice has been. The team work on which the success of radar is firmly based is in fact a demonstration of the soundness of principles long pressed in these columns as essential for scientific advance and which must be far more widely applied in industry and in Government if our scientific resources are to meet adequately the new and immense demands of peace.

The interchange of information provides a highly instructive example. The critical importance of secrecy in regard to radar is unquestionable. None the less, this overriding demand for secrecy was not allowed to obstruct or exclude that close contact of mind and free and full discussion so essential to the fertilization of ideas, to constructive and creative thought and to scientific advance. The conditions for the stimulation of scientific thought and imaginative enterprise were secured. The instrument was limited to its purpose and was never allowed to become the master; and there is no more satisfactory feature in the Government's proposals for a scientific civil service than the statement that it views sympathetically the recommendation that secrecy restrictions should be relaxed as much as possible, and scientific workers in Government service encouraged both to publish work of their own and to discuss their work with persons outside the Service engaged on similar problems.

That is a *sine qua non* of effective team work and co-operation, whether between departments, between industry, the Government or the universities. Scientific workers have given clear indications in recent months that they recognize the importance of restoring as quickly as possible full freedom of scientific communications, and it is to be hoped that neither in Britain nor in America will they miss the implications of radar but will insist on an improvement on, and not merely a return to, pre-war conditions in this respect. Freedom to know, to utter and to argue freely according to conscience is a fundamental condition of scientific advance. Radar provides a convincing demonstration that a solution of the problem of secrecy is possible on some such lines as those suggested by the Barlow Committee—that such freedom can be responsibly exercised.

A solution of this problem is essential if we are to attract to the services of the State the ablest scientific minds of each generation and if we are to make the most effective and best use of such minds in the employment of the State, of industry or of the universities. It is of course a special aspect, as the Barlow Committee recognizes, of breaking down the isolation of the scientific worker, whether or not he is employed in the Government service. Moreover, the further measures proposed for dealing with that isolation of the scientific worker in Government departments through the encouragement of mobility and interchange of staff and the introduction of the sabbatical year and the like, which the superannuation proposals of the Government are designed to assist, are exactly the type of measure equally adapted to break down departmentalism anywhere and that compartmentalism of mind whether in teaching or research to which the specialist is ever liable. Sir Robert Watson-Watt shows the brilliant success which has attended the elimination of such isolation and compartmentalism in the development of radiolocation. That very success calls for the closest study of the technique of organization by which it has been achieved, and it may confidently be predicted that the careful study of the factors responsible for such outstanding team work, and the application of the lessons of that experience in the elaboration of our post-war research structure, in Government departments, in industry and in the universities, will pay equally rich dividends.

Radar research has provided a convincing demonstration, not merely of the possibility of highly productive team work, but also of its existence side by side with conditions which favour creative work and encourage the originality and individuality, initiative and enthusiasm which are all-important in the advance of science. Here have been found and maintained exactly those conditions, those methods of treating the scientific worker so that the utmost use is made of his inherent abilities ; and no strategy of research which ignores such tactical measures is likely to achieve success. As we face the problems of reconstruction and the acute shortage of man-power which persists and is likely to remain with us, we do well to recall the reminder of an early report from the Select Committee on National Expenditure that the main need is a better use of the available forces rather than an increase in their number. Above all it is true of scientific man-power that efficient use depends not merely on having at our disposal an adequately staffed intelligence organization provided with ample means for collecting and interpreting the relevant data on the problems to be solved and determining their priorities, but also on giving to the human factor the right attention and treatment to enlist and hold its enthusiasm and highest creative and imaginative powers.

FORESTRY PROBLEMS IN THE UNITED STATES

Behold our Green Mansions

A Book about American Forests. By Richard H. D. Boerker. Pp. xvi+313+96 plates. (Chapel Hill, N.C. : University of North Carolina Press ; London : Oxford University Press, 1945.) 24*s.* net.

THIS is a book about forests in North America : forest conservation, soil conservation, timber, flood control, wild life, grazing, scenic beauty, recreation and the use of timber. All these are subjects very much under consideration at the present time, and most of them interest the general reader and all of them are of first-rate scientific importance. The subject-matter is based entirely on American experience, and brings out the scale of operations there in comparison with those in Great Britain and with the latter's small-scale problems and comparatively small climatic fluctuations. The subject is of importance in all the continental areas in the temperate zone, and the same disquieting condition is found everywhere—depleted forests causing soil movement, and an ever-expanding demand for timber.

Man's attempt at settlement in new countries has often been accompanied by a failure to recognize the dangers of interference with natural phenomena without a very detailed scientific knowledge of the factors involved. Interference with the natural cover of vegetation has nearly always been the cause disaster. This process is well seen in the Unit States where, according to the U.S. Forest Servi only seven-eighths of the original virgin forest left. This is illustrated in the work under conside tion by three diagrams of forest areas dated 16 1850 and 1942. While there is little difference betwe 1620 and 1850, the 1942 map shows these virg forest areas as very small and detached patches. is during this latter period that the problem of s erosion has arisen.

We have been accustomed to think of America a land where natural resources are so rich as to almost inexhaustible. Mr. Boerker starts by destro ing this myth regarding America's forest weal During the War, timber was classified as a criti war material, and the forests were called upon fo tremendous output of material essential to t prosecution of the War. This was met, but was han capped—as he explains in an interesting preface "by our past gross neglect of our forests". He sho how through forest fires, bad and unscientific cutti of timber, through ignorance and for quick gain, a by indiscriminate cutting down of forest lands farming, serious inroads have been made on timb resources. However, this is the negative side of t picture ; he goes on to show what is being do through conservation and re-afforestation to reme this deficiency. But as he says, "it is one thing gather scientific data and lay out a plan of actio but it is quite another thing to acquaint the fore using public with the facts". This is what this bo claims to do, and in this the author has succeed well.

The forest is treated in its relation to wild li water supply, holding the soil, flood control and as live-stock range.

With regard to wild life, the author gives e amples of the delicacy of balance between speci and quotes instances of disastrous control due ignorance of inter-relationships. In fact, mar attempts—in the absence of expert knowledge— control Nature has often been as disastrous as destruction of it for profit. This aspect is close bound up with the importance of the forest as region of recreation for the people. But with t artificial management of the forests, game laws ha to be tightened or liberalized in proportion to t food available.

The many factors affecting forests in regard water supply are complex, but broadly speakin forests conserve water and prevent rapid run- causing erosion. Not only the trees of the fore but also the ground vegetation of flowering herbaceo plants and shrubs, mosses, liverworts, lichens are interdependent and act as anti-erosion agents. northern regions these also retain snow and slow do its melting and run-off. Every type of forest has characteristic undergrowth, and the balance is oft a delicate one. Soil erosion is a world-wide proble and while much of it is due to the destruction of fore the breaking of natural grassland is equally structive in semi-arid regions, where the erosion m be due to sudden storms or more frequently to stro winds.

Of the destructive agents the author has much interest to say. While fire on a large scale is not problem in Britain, it is a real menace whe hundreds of miles of unbroken forest may occur, in America, and where much lower relative humidi is encountered than in western Europe.

Boerker gives an excellent description of such ires, which enables the reader to realize what formidable destructive agents they are. A good idea of he elaborate system of fire-watching and fire-fighting measures taken in the United States can be gathered rom this book, and the reader is impressed by the well-organized scale on which these preventive measures are carried out. In spite of all this, the annual loss of timber is very great. This is well llustrated by one example—"one of the most serious of recent fires was the big Wilson fire of August 1933 in Oregon started by friction from a steel cable passing round a dry stump. Over 260,000 acres of the finest virgin forest timber was burnt. The loss to the public and to labour was computed to be in excess of $350,000,000." In this one fire alone an amount of timber was destroyed equal in total to the entire timber cut of the United States for 1932.

To make good the wastage due to human carelessness and to almost unavoidable accident, re-afforestation has to be carried out on a similar scale by both private timber companies and the State Conservation Department. These efforts are not only designed to re-forest burnt-over areas but also to return abandoned farm land to forest.

The United States have carried out a well-planned and comprehensive scheme of juvenile and adult education on the preservation and development of their forest resources, as well as setting aside extensive areas as national parks. The work begins in the schools and is carried on later by numerous societies, of which the author mentions a number of the more mportant. The United States and Canada form one of the greatest centres of coniferous forests in the world, and although man has greatly depleted this, wise measures of conservation and large-scale schemes of re-afforestation still make the North American continent the chief area of supplies of coniferous imber.

This book is of great interest to the general reader, for it deals in a most interesting fashion with a subject hat concerns all of us. It is of equal interest to the scientific man, and appeals particularly to the botanist and the plant ecologist. A word of praise must be added for the many beautiful plates which accompany he text. Many of these were taken by the U.S. Forest Service, some by the U.S. Soil Conservation Service, and a certain number were obtained from private sources.

F. J. LEWIS.

ELECTRICITY SUPPLY ORGANIZATION

lectricity—Public or Private Monopoly?

By F. Hamlyn Dennis. Pp. iv+143. (London: Victor Gollancz, Ltd., 1945.) 7*s*. 6*d*. net.

ELECTRICITY supply takes a high place in the list of major public services which are scheduled or reorganization by the Government now in power in Great Britain. Its political prominence is not a new development, as Parliament has given considerable attention to co-ordination of electricity supply ever since the War of 1914–18 revealed the deficiencies of separate power systems serving comparatively limited areas.

The book under review provides ample information regarding the various steps which led to the existing Grid supply system, but it may be useful to summarize these steps for the information of readers not intimately connected with the supply industry.

The Electricity (Supply) Act of 1919 established the Electricity Commissioners, who endeavoured to co-ordinate the British systems by establishing joint electricity authorities which grouped adjacent undertakings to form larger and more economical units. Their efforts had so little success that it proved necessary to pass the 1926 Electricity (Supply) Act and thereby establish the Grid system controlled by the Central Electricity Board.

The Grid provides for the co-operative working of all electrical generating stations in Great Britain. It has been in operation since 1930, and has been effective in improving the average thermal efficiency by some 15 per cent. All generating plant has become generally available instead of only locally, and the savings in capital costs in power stations have offset the cost of providing the Grid equipment. During the War the Grid was of inestimable value in assuring continuity of electricity supplies throughout the country. This great technical and economic success of the Grid has been an important factor in focusing attention on the vital question of ownership of undertakings.

Mr. Dennis is a whole-hearted advocate of public ownership, and he does his best to justify his preference by revealing the fact that power companies charge more for electricity than do municipalities. He also takes great care to reveal the sources of his information, and these sources are usually the best which are available to the public. He presses home his main contention by disinterring from *The Economist* of July 4, 1936, a rather sour estimate of the efficiency of power companies: "Company-owned undertakings, by and large, have shown neither outstanding commercial efficiency in the pursuit of their own interests, nor over-much zeal for those of the consumer". This thrust would have been more effective had it been illustrated by analysing the production costs of typical undertakings. In the reviewer's opinion, the absence of such analyses conduces to inefficiency.

A 'unit' of electricity costs about 1*d*. The public are notoriously careless of pence and tolerate extortionate percentage increases of cheap articles without taking much notice.

The authorized undertakings are able to continue to operate at comparatively low efficiency because they sell much of their output directly to the uncritical and uninformed public, and because they exploit the situation to a comparatively small extent.

As a first step towards real economy in electricity supply, the reviewer suggests publication of costs of electricity to the consumer in the form of league tables. These would reveal the facts in a way which would appeal to the British public, and if they did not cause the inefficient undertakers to improve, governmental action could be taken. To ensure that there will be no premature change over to civil service control, the relative efficiencies of the General Post Office telephone service and of the power companies should be examined. The reviewer suggests that such an examination would have a sobering effect on Mr. Dennis and his co-enthusiasts.

The book is recommended as being one of the most convenient and interesting sources of information on British electricity supply.

C. W. MARSHALL.

THE JOHN INNES HORTICULTURAL INSTITUTION

THE John Innes Horticultural Institution is to move from Merton to a new site at Bayfordbury in Hertfordshire. The move will mean a radical change in the scale of work and the opportunities for studying the problems of horticulture. It is therefore worth while considering these prospects in relation to the past work and development of the Institution.

The foundation was due to a private bequest. When Mr. John Innes died at Merton in 1904, he left the greater part of his fortune to endow an institution to be set up at Merton "for the improvement of horticulture". In 1909, the Charity Commissioners approved a scheme for the new Institution which was to concern itself, on one hand, with the training of gardeners and, on the other hand, with "research, whether of a scientific or practical nature, into any matters having reference to the growth of trees and plants generally".

The administering Council represented universities and public bodies, including the Ministry of Agriculture. The first step it took was in the choice of a director. This step was decisive, for the choice was William Bateson. At this time Bateson was not only an outstanding personality in British science, but he was also engaged in the tremendous struggle—not yet won in his own country—to establish the new science of genetics. In British universities no facilities existed for research in genetics, and its teaching met with opposition rather than encouragement. To Bateson, therefore, the appointment meant a foothold, a first secure foothold, for genetical research in Britain. To the new foundation it meant a policy and a programme which filled a gap in the national development of science. At the same time, the terms of the foundation required, or ensured, that the fundamental methods of inquiry introduced by Bateson should be applied and taught on the spot. The Institution has therefore always held pure research and applied research equally balanced, using each to feed the other. Following this habit, it has always been able to attack its own problems in its own way, and its programme has been a self-propagating one.

The new theories and techniques had to be fitted into the larger framework of science, and, in the process, some false steps were taken, as indeed they were bound to be. The first appointment to the staff, however, was a success: E. J. Allard, a fine gardener and a wise teacher, was made curator. From the first, too, the genetic work with fruit crops met with success. M. B. Crane, who was one of the earliest products of the new training, was put in charge of this branch in 1919. The full possibilities of plant breeding, however, waited upon the second decisive step in the development of the Institution This step was taken by Bateson following his visit t the headquarters of the *Drosophila* school in 1921 He then realized that the next great advances i genetics would demand that the study of chromosomes should go hand in hand with experimenta breeding. He accordingly invited the late W. C. F Newton to establish this second new theory an technique at Merton. Once again a serious gap in th national scheme of research was filled by Bateson' initiative. A school developed, and foreign worker played an important part in its growth. Vavilov an Sturtevant, and later Karpechenko, Belar an Müntzing made their varied contributions to th work; and the visits of Johannsen and Morgan Lotsy, Winge and Mohr, Driesch, Baur and Goldschmidt enlivened the frequent and often length arguments in the library, laboratories and fields a Merton.

BAYFORDBURY, THE NEW HOME OF THE JOHN INNES HORTICULTURAL INSTITUTION

After Bateson's sudden death in 1926, the sam policies were continued by Sir Daniel Hall. But ver naturally a synthesis also began to take place ndelian experiment and chromosome observation re combined in the work of J. B. S. Haldane and, a different way, in that of C. D. Darlington. The ndations of plant breeding, especially in the fruits, re changed by the discovery of polyploid series ated in various ways to hybridization and recom- ation, as well as to fertility and vigour. At the ne time, to meet the exacting needs of plant eding, improvements in the quality and precision glasshouse cultivation were demanded. W. J. C. wrence, Allard's successor, and a second of the stitution's own students, achieved these improve- nts, and the fruits of his success have been reaped the industry at large.

In October 1939 Sir Daniel Hall was succeeded as ector by C. D. Darlington. In spite of war condi- ns, K. Mather, now head of the Genetics Depart- nt, was able to introduce and perfect another new entific method. It was based on applying the ndelian and chromosome theories in combination h Fisher's statistical methods. It made use of allel studies on quantitative inheritance, or con- uous variation, in the fly *Drosophila* and in crop nts. The results have an undoubted practical ring on plant breeding; and they also have the damental value that they finally reconcile the d-dying conflicts of Darwinian and Mendelian ory, of biometry and genetics. During the same iod, at several angles, chromosome studies have n shown in their broad and fundamental bearing medical research, in the recognition, etiology, and ray treatment of cancer, and in the understanding the development of the blood. With new methods study of the cell is proving to be as useful in the proach to development and disease as it has been the approach to heredity.

During the War, the scientific staff was reduced m sixteen to six, and long-term projects had of rse to be replaced in part by more immediately ful trials and experiments. The practical results this work have been made known to the grower d cultivator by leaflets, bulletins and by advisory vice. These activities will doubtless have to remain er the War: it is clearly not enough for the harvest research to be stored—or buried—in libraries. ture developments, however, will depend on the cess of the major operation of transplanting the stitution and on its economic situation afterwards.

When the permanent buildings, laboratories and sshouses were put up in 1910, it was already own from A. D. Hall's report that the site and soil re poorly suited to the purpose. Both went from l to worse. The vicinity was clothed with suburb er the last War; the air was polluted, the sunlight down, the water-table lowered, the garden pests ltiplied and strengthened, while miles of houses d factories cut off all avenue for expansion and all tact with the one industry that mattered. As t as its building value went up, the horticultural ue of the land went down. The workers outgrew laboratories, the books outgrew the library, the eriments outgrew the gardens. Setting up over- w stations could merely postpone the decision. ew site had to be found.

nquiries for new land were begun in 1938. They tinued over a wide area for seven years. The lity and drainage of the soil, the atmosphere and nate, the water and electricity supply, the availa- ty of buildings, the accessibility to town and versity, all had to be taken into account. Com- cial value also had to be regarded. The Institution's revenue, reduced in 1931, was still further curtailed in 1941 by the war damage in London, which was even more serious in its financial effects than the direct destruction at Merton in 1944.

The John Innes Trustees have chosen a site which meets these various requirements better than had seemed possible. They are exchanging 19 acres at Merton for 372 acres on the new site. While Merton is eight miles from the centre of London, Bayfordbury is sixteen miles away. It is one mile from Bayford Station and less than a mile from the outskirts of Hertford. Yet the district, for the last hundred years, has been unfashionable enough to have remained rural. Indeed Bayford (to quote the Greater London Plan, 1944) "is in the centre of a very extensive belt of woodland . . . one of the few really unspoilt tracts of land near London, from which it is readily accessible". The soil is based on glacial drift over chalk and varies from a light to a medium-heavy loam. The land lies on the south side of the River Lea, and rises a hundred feet above it. The slopes should give safety from frost without undue exposure to wind. Conditions so favourable as these are not easily found near London.

Bayfordbury was built in the years after 1759 by William Baker, nephew-in-law of Tonson, the publisher of Milton and Dryden. Until this year it housed the collection of Kneller's portraits of his forty-two friends or clients, members of the Kit Cat Club, which has now been acquired by the nation. The profits of "Paradise Lost" paid for a substantial building. The mansion is conveniently designed and centrally placed. It is handsomely sited between two groups of cedars of its own age. A lake near by, fed by surface drainage, affords a plentiful supply of water for irrigation. The woodlands include the collection of conifers, occupying ten acres and recorded in the four-volume work of Clinton-Baker and Jackson. This collection was established in 1838 by W. R. Baker with the advice of Loudon. Now it might well prove of value in the study and breeding of both ornamental and timber trees.

The mansion and outbuildings provide nearly twice the accommodation at present available at Merton. Some of this will be useful for domestic housing. But even with the six additional cottages it will clearly not go far towards solving the housing problem. With their dependants, the staff number, in peacetime, about 120, and under present conditions their removal as a whole to a new locality will demand new housing. The necessary building will probably not be completed for two years or more.

The question remains as to why such a sudden expansion of area is made. Can profitable use be made of so large an area for horticultural, and especially genetic, research? The original land purchased at Merton was five acres, and only piece by piece were acres added to it—so long as they could be added, and always at an increased price. Other research stations have suffered from outgrowing their land after twenty or thirty years with like consequences. The Royal Botanic Gardens, Kew, were larger and the difficulty came late but, having come, proves insuperable. With the Royal Horticultural Society's gardens at Chiswick the difficulty was overcome by removal; and the new gardens at Wisley, like those at Kew, are of similar size to Bayfordbury. Of the 372 acres in the new estate, no more than 150 acres will, it is expected, be taken up for research purposes in the next ten years. But the choice of a larger area for the John Innes land is based on the expectations of fifty years. It is also based on the view that the need for research, and the understanding of that need, are likely to grow beyond our present computations. This view takes into account two lessons of the war period. One is that horticulture has changed from an incidental luxury into a necessary part of the nation's economy. The other is that genetics has changed from an ornament of research to one of the main props of science.

In its new habitation, the John Innes Institution will undoubtedly undergo a transformation. But there seems no reason why it should forsake the character or the aim for which it has been valued. Its aim will no doubt continue to be to unite theory with practice and to combine a freedom of initiative with some coherence of purpose within the wide range of activities allowed by its foundation.

THE TEACHING OF ANALYTICAL CHEMISTRY IN GREAT BRITAIN: WITH SPECIAL REFERENCE TO MICROCHEMISTRY

By Dr. CECIL L. WILSON

FOR some time past it has not been possible to make any accurate estimate of how the demand for microchemical teaching in the British Isles has been met. Previously, the only guide in this direction was the list, probably not altogether comprehensive, published from time to time in *Mikrochemie* before the War. As a consequence, discussion of the teaching of microchemistry must of necessity have been based largely on estimates derived solely from personal contacts and hearsay, and any statement about it was justly open to doubt.

The only satisfactory way to clear up the position was by means of some sort of census. This was scarcely an undertaking for a private individual. The recent formation of the Microchemistry Group of the Society of Public Analysts and Other Analytical Chemists, however, provided an official body to which the information is of first importance. At the request of the Committee of this Group (under the chairmanship of Prof. H. V. A. Briscoe, Imperial College of Science and Technology, London), therefore, a questionnaire was drawn up, the answers to which would clarify the position of the teaching of modern analytical methods, and, in particular, of microchemistry. This questionnaire has been circulated to 85 centres of higher chemical education in the British Isles, comprising 43 universities, university colleges and university institutes, and 42 technical institutions. Replies have been received from 64 of the institutions —75 per cent of the total covered—made up of 32 universities and their institutes and 32 technical colleges. The information contained in the replies has been collated, and forms the basis of this report.

It was difficult to draw up a questionnaire which would cover the situation both completely and in detail. In fact, study of the replies suggests that such an achievement would have been impossible. But it must be acknowledged that most of the institutions received the questionnaire in an extremely helpful spirit, and did their best to interpret doubtful questions so as to supply the maximum of useful information. Many institutions made valuable additional comments, and it is perhaps in these that most food for thought will be found.

In spite of this co-operation, some points w
missed completely, while others still remain vag
For example, as was pointed out in one reply,
question which should have been asked, and was n
concerned the number of microchemical balan
possessed by each institution. Answers to this mi
conceivably have been useful in clearing up cert
vagueness in other replies. Again, confusion
nomenclature, more particularly as between
terms 'micro' and 'semi-micro', is apparent; wh
some institutions probably put a much wider int
pretation than was intended on a question wh
asked for information about *special* courses deali
with modern analytical techniques. This gives
to doubts as to whether the teaching of any of t
more modern techniques is really as advanced as
suggested by a superficial study of the replies.

As a consequence, it has been necessary, in repo
ing, to interpret equally broadly on occasion. But
is felt that, at least so far as microchemistry is c
cerned, this summary presents a much more cohere
and truthful picture than has hitherto been availab
Where it has been thought desirable, distinction
been made between the technical colleges and
universities, as the conditions ruling in each of th
groups, and controlling their activities, are marke
different in many ways.

Modern Analytical Methods

Of the 64 institutions replying, 25 normally tea
electrochemical analysis, 16 teach spectrograp
analysis, and 25 teach electrometric methods. O
or two of these courses of instruction have be
interrupted owing to the War. In addition, 5 insti
tions teach the use of the polarograph, 12 colorimet
photometry, 2 metallurgical analysis, and 10 rep
miscellaneous or unspecified courses.

It is probable, as already suggested, that in ma
cases this instruction merely forms part of an existi
course in general chemistry, and is not a spec
course. There are, however, certain institutions
replies from which indicate clearly that in their c
the courses *are* special ones dealing only with
methods specified, in a reasonably detailed fash
Only 3 of the institutions replying possess a spec
lectureship in analytical chemistry. However,
other institutions find it necessary to qualify
negative reply by stating either that they have
lecturer concerned solely or almost solely with t
branch of work, or that such a lectureship is desira
or projected.

Microchemistry

In all, 43 of the institutions, that is, almost 70
cent, have taught or teach microchemistry in so
form or another.

The first course in microchemistry in Brit
appears to have been established in 1929. Of the
institutions which give a date for the commencem
of their course or courses, 16 started prior to
War, only 4 since. This is quite to be expected.
peak years for new courses were around 1936–38.

Estimates were given by 22 institutions of the ti
spent on micro work. These estimates range, rat
startlingly, from 4 hours per student to 300 hou
Examining these figures rather more closely,
average value for the 22 institutions is just over
hours per student. Of the individual estimates, 6
above the 100-hour mark, and 12 above 50 ho
Rather surprisingly, these figures are distributed fa
equally between universities and technical colleges

In Table 1, which indicates roughly the grading of he courses, those referred to as "current" are running t present. Those designated "pre-war" were in existnce before the War, but have since been suspended. hus the total of these two gives some measure of the robable *minimum* number of courses which would be n existence at present, had it not been for the War.

TABLE 1.

	Universities	Technical Colleges	Total
pecial Postgraduate Courses:			
Current	4	3	7
Pre-war	1	5	6
Total	5	8	13
pecial Undergraduate Courses:			
Current	2	3	5
Pre-war	1	1	2
Total	3	4	7
outine Instruction to Undergraduates:			
Current	11	10	21
Pre-war	6	5	11
Total	17	15	32

As this shows, of 64 institutions, there should be, fter the War, at least 52 potential courses in the ractice of some form of micro methods—25 in niversities, and 27 in technical colleges. In fact, his figure is almost certainly an under-estimate, as everal institutions report projected courses, not ncluded in Table 1, which have not yet materialized ecause of the War.

The outstanding point that is brought out here, owever, is the impressive number of institutions—0 per cent—which have found it advisable to introuce microchemistry to some extent as routine ractice for students. This is concrete proof—perhaps he first to be produced—of the appeal and usefulness f micro methods in teaching in Britain. It gives very justification for the recognition of these methods y examining bodies which control external examinations, thus enabling those institutions which teach or such examinations to do so on an equal footing with those which include microchemistry in courses or internal examinations, and with an equal claim o modernity.

Further details of the type of instruction are abluated in Table 2:

TABLE 2.

	Universities	Technical Colleges	Total
uantitative Organic Analysis	13	15	28
ualitative Inorganic Analysis	9	18	27

Quantitative Organic Analysis	13
Synthetic Organic Methods	7
Qualitative Inorganic Analysis	5
Quantitative Inorganic Analysis	4
Qualitative Organic Analysis	4
Physicochemical Methods	2

In the case particularly of the qualitative and nthetic methods, there seems to be considerable nfusion over a distinction between the two scales 'micro' and 'semi-micro'.

In preparing a general report such as this, it is most impossible to give any closer indication of the pe of instruction which prevails. It is felt, however, at it would be of interest to detail the instruction ven at one institution, of moderate size, serving a wn of average population (about 50,000–60,000). his institution, one of the more advanced in this respect, is not, however, necessarily the best. It is chosen rather as showing what can be undertaken by an institution which has only average resources of space, staff and finance, where the will to progress is present. Special courses deal with electrochemical analysis, electrometric methods of analysis, including the use of the "magic eye" apparatus, and absorptiometry. In general analytical chemistry, apparently a special postgraduate course, the following are dealt with: application of organic reagents to inorganic analysis; chromatography; polarography; the electrograph; use of luminescent, redox, adsorption and complex-forming indicators; the high-temperature combustion furnace; survey of the branches of microchemistry, etc. Coming to microchemical courses, these are held both as special undergraduate courses and as part of routine instruction to students. The branches covered include qualitative inorganic analysis, qualitative organic analysis, quantitative organic analysis, physicochemical measurements; synthetic organic methods are to be introduced soon, and quantitative inorganic analysis is taught on the semi-micro scale. The special course occupies two hours per week for its duration. The special remarks section states: "We are teaching micro-methods to National Certificate Students. A special course for final students and graduates is run in the Summer Vacation. It is hoped to extend it to 'outside' people this year".

The reasons given for absence of any, or of fuller, instruction in the various institutions occur in the following order of importance: lack of time (25); lack of staff with the appropriate knowledge (16); the War (14); lack of space (14); lack of apparatus (13); small educational value and limited uses of microchemistry (6). Certain of the answers—lack of staff, lack of space, lack of apparatus—are in some cases qualified by "during the War", these necessities having been loaned for national use.

The last category—small educational value and limited uses—must be read with some reserve, since of the 6 institutions putting it forward, 2 already teach some microchemistry, and 2 others propose introducing some after war conditions have eased.

As already remarked, the additional comments kindly supplied by the different institutions provide much that is of interest. The more important issues which they raise are best illustrated by quotation. Two divergent views of the value of microchemical instruction provide a striking assessment when taken in conjunction: "From educational standpoint, favour Inorganic micro in Third Year". "Micro and semi-micro technique is not taught for its own sake, but merely to improve the experimental technique of the students—mostly with a view to the saving of time". On the other hand, it is stated, "Many of our research investigations demand a good working knowledge of microchemistry in all its branches". "In chemical practice one so frequently has to deal with small quantities". In other words, microchemistry has proved its usefulness, whether it is considered solely as a teaching method or as an analytical tool.

A few of the institutions which already include some microchemical teaching doubt the wisdom of introducing more; but a considerable majority intend to increase substantially the time devoted to the subject when conditions permit.

The low regard in which analytical chemistry tends to be held is specially commented on by several writers: "Modern analytical methods should figure much more prominently in the curriculum of a Technical College than is customary at present". "*Academic* Institutions tend not to give much attention to chemical analysis. It is often quite difficult to make students do *any* accurate work".

Pleas are made for the provision of teaching *for the teacher*. "Vocational courses held at some suitable centre, for the training of teachers in the various branches of microchemical analysis, would be much appreciated". "It is desirable that a summer school for teachers should be established so that they may acquire a first-hand knowledge of the technique required. Prior to the War, such training was difficult to obtain in the British Isles".

The difficulty of the external examination is pointed out: "The chief determining factor is undoubtedly that the University of London and professional bodies generally do not yet demand a knowledge of microchemical technique in their practical examinations". "Omitted of late, since students have to complete their studies in less time than before"; that is, discarded as the first inessential for examinations!

Finally, one comment may be coupled with the difficulties of those who plead lack of apparatus: "For quite a year now we have been unable to do micro organic analysis for research purposes, on account of the balances needing attention. It has not been possible to get even one of the three balances reconditioned".

Without further comment, it may be claimed that a number of conclusions are implicit in this survey. In the first place, there is undoubtedly a general recognition among teachers of the importance of analytical chemistry in general, and microchemical methods have obviously recommended themselves strongly to teachers as a useful instructional topic. Recognition of this by the professional and other examining bodies is desirable, particularly in view of the probable post-war development. Every effort ought to be made to secure this recognition, and to make possible further development of the regard for analytical chemistry in teaching institutions.

In this connexion it is perhaps worthy of stress that the size of the institution and the importance of the area which it serves seem to bear no direct relationship to its attitude to analytical and micro methods. In other words, small institutions are as advanced in this respect as larger ones, whether one considers the apparatus available or the nature and extent of the instruction. Presumably, therefore, development in analytical and microchemical teaching may be regarded as a function of individual endeavour, and further improvement in this respect is not altogether dependent on such physical factors as available funds.

Some provision should obviously be made for refresher courses in analytical chemistry of varying scope, arranged primarily, but not necessarily solely, for the benefit of teachers. It is out of the question for Britain to regress, in the next few years, to the pre-war condition of being almost entirely dependent on Central Europe for such a prime necessity.

In conclusion, it may be claimed that a subject which is regarded by 50 per cent of the more important teaching institutions of the British Isles as worth teaching cannot in future be considered to be beneath the notice of the chemist in general.

It is impossible to thank personally all those teachers who took pains to fill up the questionnaire, and to supply valuable further information. Grateful acknowledgment of their help is therefore made here.

NEW BASIC CONCEPTS IN ELECTROCARDIOGRAPHY: THE VENTRICULAR GRADIENT

By DR. W. F. BERG*

CLINICAL, anatomical and experimental researc have all collaborated to make electrocardi graphy indispensable for the clinician. The natu and origin of the various irregularities of the hea rhythm can be diagnosed with accuracy. Since che leads have been introduced, one can get detaile diagnoses of heart muscle lesions, such as result fro an occlusion of the arteries supplying the hea muscle. Similarly, we are able to locate lesions with the specific nervous system of the heart known the bundle of His and its branches. It is even possib to diagnose toxic changes so small as to escape th methods of the pathologist. An important advan has more recently been achieved by the introducti of a new basic concept by the American worker F. N. Wilson[1] and his school. This has found almo immediate practical application.

In the state of rest the heart, in common with a muscles, consists of polarized cells: the insides of th cells carry electric charges which are neutralize by charges of opposite sign surrounding the cell The regular excitation and relaxation causes rhythmic sequence of waves of electric depolarizatio and repolarization to pass through the heart muscl Thus, at any one moment potential differences a set up between two points of the body; these ca be measured by any instrument which is sufficient sensitive. At any one instant the heart may likened to an electric battery, the poles of which a inserted into a conducting medium, the body; suc an arrangement is characterized by the direction a line pointing, say, from the negative to the positi pole, and by the strength of the poles. Thus th electric excitation of the heart muscle is best describe by an arrow possessing both a direction and a length this arrow is known as the instantaneous electric ax or heart vector. In order to determine this vect the following assumptions are commonly made.

In the standard procedure the current produce by the heart is recorded by an instrument of sho period such as a string galvanometer or cathode ra tube, which is connected in turn to two out of thr points: the left arm (*L.A.*), the right arm (*R.A* and the left leg (*L.L.*). Electrically the heart is co sidered to lie in the centre of an equilateral triangl which is large compared with the dimensions of th heart and which is named after Einthoven. Recor obtained simultaneously in two 'leads', say betwe the left and right arms, and the left arm and l enable the instantaneous heart vector to be dete mined by the construction indicated in Fig. 1. Th method is based on the consideration that th deflexion of the instrument in one lead is proportion to the projection of the heart voltage on to a straig line connecting the end points of that lead. Th the deflexion in each lead at any one instant is th component of the vector in the direction of the lea line as marked inside the triangle. Verticals a erected at the end point of each component on a lea line. A line drawn from the centre of the triangle the point where the verticals from two componen cross constitutes the instantaneous vector. If d flexions are obtained in three leads simultaneousl

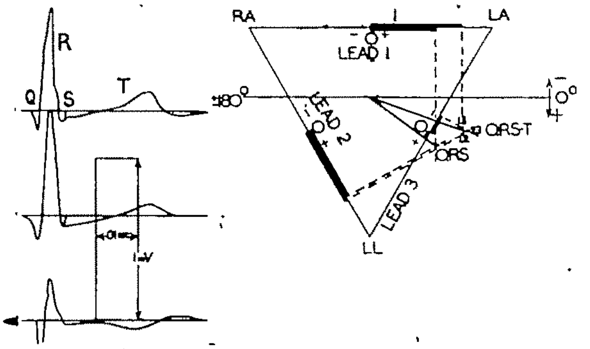

Fig. 1. PRINCIPLE OF THE HEART AXIS DETERMINATION.

(1), (2) and (3) are records obtained in the three leads. The figures in the table are the areas under the various parts of the records

	Lead 1	Lead 2	Lead 3	
	− 3 2	− 6·5	− 7·0	Calibration
	+37·5	+48 0	+10 5	
	− 2·5	− 1 5	0·0	0·1 mV. sec.=248
	− 5·0	−10·5	−16·0	1 μV. sec.=2 48
	+19·5	+12·5	+ 3·0	
	− 3·5			
RS	+31·8	+35·0	+ 3·5	
RS—T	+42·8	+37·0	− 9·5	Resultant
RS/2·48	+12·6	+14·1	+ 1·4	87° 15·5 μV. sec.
RS—T/2·48	+17·2	+14·9	− 8·8	20° 18 9 μV. sec.

hree end-points are obtained for the vector; these points should coincide if the Einthoven condition is fulfilled. The heart vector so determined constitutes he projection of the vector in space on to the plane determined by the three lead points[2].

Displacements of the heart as well as pathological changes influence the directions and the lengths of the heart vectors, and considerable variations are found. A certain degree of order has been introduced by the new concept due to Wilson[1] and his collaborators, and termed by them the 'ventricular gradient' (*G*); this means the average electrical activity during the excitation and contraction of the heart chambers, the averaging process being carried out over time, direction and length of the instantaneous vectors. Whereas the length of the instantaneous vectors is measured, say, in micro-volts, the dimensions of the average vector is in micro-volt seconds. Average vectors may be obtained for any part of the heart-cycle which can be recognized with certainty in each lead. Thus an average *QRS* vector is sometimes utilized[3], these letters referring to the first peak part of each record (Fig. 1).

The average vectors are obtained as follows Fig. 1). The areas under the different parts of the electrocardiogram *Q*, *R*, *S* and *T* are tabulated and added to give the total areas of *QRS* and *QRS-T* = *G*). These totals, standardized by dividing them by the area corresponding to 1 μV. sec., constitute the omponents of the average vectors along the sides of he Einthoven Triangle and are here marked by heavy lines, inside the triangle for *QRS*, and outside he triangle for *QRS-T*. The resultant vectors are shown and their length and direction can be read from the diagram.

The ventricular gradient is a concept of fundamental importance in the physiology of muscle action-currents. Depolarization and repolarization f the cells in the muscle are brought about most probably by movements of the same ions across cell membranes and back again. In a homogeneous muscle fibre the total electric activity due to depolarization must be equal and opposite to that rought about by the repolarization. This is true wherever the place of the original stimulation may be, since the waves of excitation and relaxation merely follow one another with opposite signs. If now the fibre considered is not homogeneous, but for example the systole—the state of contraction before relaxation sets in—lasts longer in one part of the fibre than in another, the total electric activities of excitation and relaxation may no longer be equal and opposite: the fibre now exhibits a 'gradient' of average electric activity. Records obtained from three equidistant points of a surrounding conducting medium would allow this gradient to be determined. Again, the direction and length of the gradient is independent of the point and method of stimulation of the fibre. This conclusion was beautifully confirmed by Wilson *et al.*[1] on a dog's heart. They cut the fibres along which excitation is normally conducted, so that excitation had to spread through the mass of the heart muscle. This altered completely the character of the electrocardiogram, but the gradient was not affected. Thus, "the ventricular gradient is the fundamental quantity in electrocardiography"[3]; generally speaking, it points from the part of the heart where systole is longest to where it is shortest.

A very thorough study of the ventricular gradient and the mean *QRS* vector has been carried out by Ashman and Byer and collaborators[3] on more than five hundred persons whose hearts were considered from clinical investigations to be normal. This large amount of material allowed the different factors influencing the mean vectors to be investigated. The average value for the gradient *G* is 52 μV. sec., for the *QRS* vector 25 μV. sec., being slightly smaller for women than for men. There is a distinct correlation between the size of the *QRS* and the *G* vectors: *G* tends to be about twice *QRS*, although many other factors influence the relationship in any one particular instance. The value of *G* decreases with increasing heart-rate *H*, the average over a large number of persons following a straight-line relationship which may be expressed as $G = 92 - 0{\cdot}5\,H$. Acceleration of the heart-rate by amyl nitrite or by exercise causes a change corresponding to this relationship, but a change from the recumbent to the supine position causes *G* to decrease very much more than corresponds to the resulting acceleration of the heart. This variation of *G* with posture is probably connected with a displacement of the heart, which tends to assume a more vertical position in the upright body.

A great deal of consideration was given to data which would allow the position in space of the *QRS* and *G* vectors to be derived from their projection on to the frontal plane as determined from the records. The assumption on which these considerations were based was that in the various normal hearts investigated, the *QRS* and the *G* vectors in space were identical with respect to length and relative position to one another and to the heart itself, and that the differences in length and direction of these vectors as projected on to the frontal plane were due to variations in the position of the heart in the body. Various indications as to the position of the heart were utilized, such as X-ray radiographs and relationships already established between the appearance of the *QRS* complex and a rotation of the heart around its longitudinal axis. The problem is very similar to that known to X-ray crystallographers: many data are available, but it is impossible to derive the configuration directly from these data. A shrewd guess guided by these data had to be made. The longi-

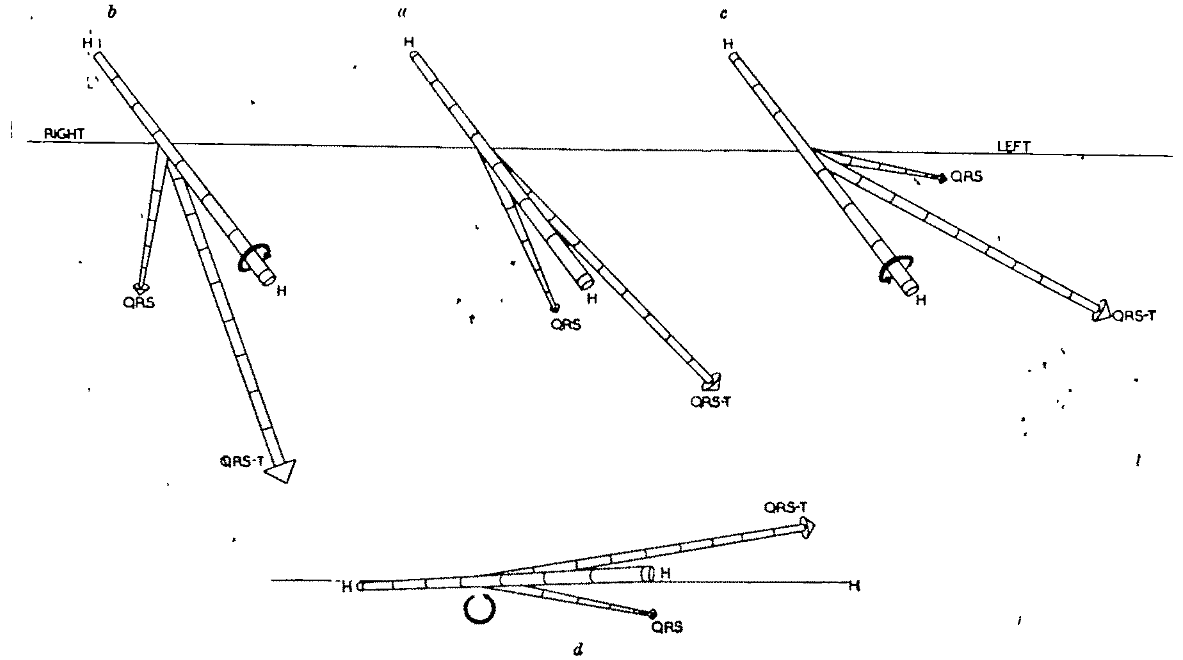

FIG. 2. VARIOUS POSITIONS OF THE HEART, CHARACTERIZED BY ITS LONGITUDINAL AXIS H—H AND THE RESULTING POSITIONS OF THE TWO AVERAGE VECTORS AS PROJECTED ON TO THE FRONTAL PLANE.

(*a*) is a heart in a normal position, (*b*) rotated clockwise around the longitudinal axis, (*c*) rotated around the same axis anti-clockwise. (*d*) is the heart as shown in (*a*) rotated around an antero-posterior axis as a result of pneumo-peritoneum.

tudinal axis of the heart, normally pointing slightly forward and to the left, the gradient and the *QRS* vector lie nearly in one plane. The gradient lies backwards from the longitudinal axis forming an angle of 60°, and *QRS* lies back still farther, making an angle of 90° with the axis. The length of the gradient is 92 μV. sec., that of *QRS* 44 μV. sec. A model of the heart with these vectors attached was projected by light on to a sheet of paper representing the frontal plane, and thus the various relationships between the measured values for length and position of the vectors could be checked up. Very good agreement was obtained between the directions of the vectors and their length as determined in the frontal plane. Typical results are indicated in Fig. 2. Here (*a*) indicates a typical normal heart, in which the anatomical heart axis is indicated by *HH*. The most common variation in human hearts is a rotation about the anatomical axis; where this is clockwise, as viewed from the apex towards the base, *QRS* appears to the right of *G* (Fig. 2*b*); where it is anti-clockwise, *QRS* lies to the left of *G* (Fig. 2*c*). Master[4] has published a thorough study of the correlation between the shape of the heart silhouette and the electro-cardiogram. Ashman and Byer[3] have evaluated his electro-cardiograms by vector analysis and added cases of their own. On the whole, the agreement is astonishingly good, and the model put forward by these authors to represent the relative positions of the vectors with respect to the heart would appear to be generally valid for a normal human heart.

Acceptance of this model thus provides a means for studying displacements of the heart using electro-cardiographic records. This method is all the more valuable where the displacement is so large that an investigation of the heart silhouette ceases to be a reliable guide. This difficulty arose in the course of an investigation by Benatt and myself[5] on the electrocardiogram in pneumo-peritoneum. This treatmen which was introduced into Great Britain by Cliffor Jones and MacDonald[6], is now applied widely in th treatment of tuberculosis of the lung, and consists i the induction of a litre or more of air into th abdominal cavity just below the diaphragm. A co siderable rise of the diaphragm then displaces th heart, which often becomes quite unrecognizable i the X-ray silhouette. The electrocardiogram was ver similar to that obtained with severe heart musc damage, but in the absence of any clinical symptom and since the pattern was completely reversible, was concluded that the new pattern was due to mere displacement of the heart. Vector analysis wa applied and both *QRS* and *G* vectors were found t deviate very strongly to the left, as indicated i Fig. 2*d*. The heart therefore must carry out a simil rotation around an antero-posterior axis, togeth with less important movements the description o which would take up too much space here.

Thus the new concepts of average electric hea vectors, and in particular of the ventricular gradien are beginning to play an important part in electr cardiography. After the fundamental groundwo has been done, applications to clinical work are no forthcoming. In his latest paper Ashman[7] discuss one of the most important signs of heart disease i the electrocardiogram, the so-called deviation of th *S-T* segment from the zero line, in relation to th magnitudes of the *QRS* and *G* vectors. More an interesting work is bound to follow from this line o thought.

In conclusion, a word regarding the organizatio of this research may not be out of place. It is n accident that all the research summarized above the result of team-work, and that the team include a physiologist or even a physicist. Work in th border region between medicine, physiology an physics usually requires collaboration. Research o his nature is a fine example of what the late Sir Thomas Lewis, the master pioneer in electrocardioraphy, has termed 'clinical science'. "The boundaries between individual sciences may not be mainained without hindering progress; overlaps between Clinical Science, pathology and physiology are vital o medical science as a whole; they bind together hree activities which in process of time have grown too far apart from one another"[8].

REPEATING COMPASSES

By W. E. MAY

FROM time to time paragraphs appear in the Press on the subject of compasses in aircraft. They usually take the form of a complaint of the inaccuracy of magnetic compasses in general, followed by praise of some invention which is said to surmount all difficulties. The new instrument is often improperly described as a 'gyro-compass'. It is not the purpose of this article to advertise or condemn any of these inventions, but to enable the reader to see in proper perspective the claims which they contain.

For nearly a century, inventors have striven to perfect a repeating magnetic compass, that is to say, a compass the indications of which are automatically ransmitted to a point or points at some distance. Many methods of obtaining signals from an ordinary magnetic compass in order to work a repeater system have been tried. Among these may be mentioned he forms using selenium cells, intermittent positive contact between contact on the card and in the bowl, or a Wheatstone bridge principle using electric currents passed through the liquid in the bowl. All need some form of signal amplification which may be obtained by the use of valves or relays.

When we talk of a magnetic compass we are apt o think only of the ordinary instrument containing a needle which aligns itself with the direction of the lines of magnetic force; but there is a second type which particularly lends itself to the provision of a epeating system. That is the earth inductor or otating inductor compass, which depends on the principle that if an armature, similar to that of a mall electric motor, is rotated about a vertical axis in the earth's magnetic field, it generates a current. This current can be tapped off in the ordinary way by means of a commutator and brushes, the strength and direction of the current in the external circuit being determined by the orientation of the brushes elative to magnetic north. There will be a relative brush position where no current flows in the external circuit.

Thus by various means both the needle and earth inductor types of repeating compass give a signal as oon as the bowl (or other follow-up unit such as the brush carriage) is out of step with the directional element. This signal can be made use of in two ways. In the simple form the bowl is turned by means of a Bowden wire to the position corresponding to the course desired. When the aircraft is off her course, a simple indicator shows the pilot which way to steer to get back.

In the more ambitious arrangement, the directional signal is used to control a follow-up motor which drives the bowl round until the position of 'no signal' is reached. At the same time it drives a step-by-step transmitter through gearing, and this transmitter drives the repeaters electrically so that they indicate the orientation of the bowl and consequently the course of the aircraft.

Another type of repeating compass may be styled the static inductor type. In this type an alternating electric current is passed through a coil wound on an iron alloy core bent into a triangle or other shape. This core is fixed in the aircraft with its plane horizontal. According to the course of the aircraft, the various sides of the core will be magnetized in a greater or less degree by the magnetism of the earth. The fact that the sides thus become magnets of differing strengths upsets the balance of the alternating currents in the parts of the coil wound round them, thereby causing varying currents to flow in wires which are tapped off the coil at intervals. These tappings are led to coils in the repeater where they set up a magnetic field. A magnetic needle lines itself up with this field and thus indicates the course of the aircraft.

A combination of the needle and static inductor type of compass is also sometimes used. This is similar to the static inductor type, but contains in addition an ordinary compass needle of rather high magnetic moment. The needle points to magnetic north and also serves to induce magnetism in the core of the inductor.

A type of compass which is often referred to nowadays is the gyro-compass. This compass depends on the fact that a perfectly balanced gyroscope will always tend to keep its axis pointing in a fixed direction in space. This of itself would be of little value as a direction indicator, since the earth's rotation will produce a continuous variation in the direction of the axis relative to the meridian. The gyroscope can, however, be made to act as a compass by the introduction of some form of control, so that this fixed direction in space is amended until the axis is horizontal and pointing along the meridian. In the true gyro-compass, this is effected by using the rotation of the earth to harness the force of gravity to the gyroscope.

The arrangement is perfectly satisfactory in a ship of moderate size, but in aircraft the higher speeds and greater manœuvrability produce accelerations introducing a varying false vertical and upsetting the control. All attempts to use gyro-compasses in aircraft have consequently been failures.

The gyroscope, as distinct from the gyro-compass, has, however, a use in aircraft. We have not been able to produce a gyroscope so well made that it will give a perfect performance with its axis maintaining a fixed direction in space indefinitely, but we can make one which will maintain its direction for a matter of minutes. It will be appreciated that having no gravity control, this gyroscope will be unaffected by the movement of the aircraft. If now we link any form of repeating magnetic compass to this gyroscope, so that the latter is controlled by the former, the gyroscope will tend to line itself up with the magnetic compass; but as its rate of precession is much less than the rate of oscillation of the compass, it will actually line itself up to the mean direction of that instrument. In this way, by using a magnetic compass to control a gyroscope and the gyroscope to control repeaters we get a combination, known as a 'gyro-magnetic compass', which smoothes out most of the erratic oscillation of the ordinary compass.

Another application of the gyroscope is sometimes used. In those static inductor compasses where the core is magnetized by a compass needle, it is convenient to use a double-axis needle, that is, one which is mounted on a vertical axis instead of being free to dip as in the ordinary compass. This method of mounting introduces difficulties, because if accelerations cause the axle to leave the vertical, the vertical force of the earth pulls down on the north end of the needle, thereby deflecting it from north and causing an error. By introducing a gyroscope into the instrument it is possible to use the gyroscope to stabilize it so that the axle of the needle will always remain truly vertical.

When speaking of gyro-magnetic compasses it must be clearly understood that they are fundamentally magnetic compasses and not gyro-compasses. Although they have the advantage of smoothing out oscillations, they still point to the magnetic and not to the true north. The master compass must be fitted in a position as remote as possible from magnetic disturbance. The aircraft must be 'swung' to adjust the compass in the ordinary way, and rather more than ordinary care is required to do this effectively. Finally, a deviation table must be obtained and the deviations applied to *all* repeaters when using them.

The statement that the gyro-magnetic compass indicates the magnetic rather than the true north must be qualified. In some systems a variation-setting corrector or other device is provided. This is a link in the repeater system which enables the repeaters to be put out of step with the master in a convenient manner. If the variation is kept set on this device, the repeaters will show a heading differing from true by the deviation. If the variation plus deviation is kept set, the repeaters can be made to indicate true north, but it will be noted that this does not mean that the swinging of the aircraft for compass adjustment can be dispensed with.

We can now summarize the several points to be considered when judging the relative advantages of the various systems. They are : (1) A needle compass is liable to be affected by accelerations and movements of the aircraft, that is, by swirl error, northerly turning error, etc. (2) All types of magnetic compasses, whether they be needle or inductor or a combination of both, indicate the direction of the magnetic field at the compass position, and not necessarily the magnetic meridian. It follows that they all have deviations which must be allowed for or corrected. (3) Repeating compasses can be placed in better positions from the magnetic point of view than those positions from which the aircraft is controlled. (4) In repeaters other than those driven on the step-by-step principle, the needle is apt to be made to oscillate by shocks and accelerations. The repeaters, however, are self-synchronous so do not need lining up when the compass is switched on. (5) Inductor compasses are less sensitive than needle compasses. (6) Gravity controlled gyro-compasses cannot be used in aircraft. (7) Gyro-magnetic compasses require adjusting like any other magnetic compasses, but smooth out swirl and northerly turning errors. (8) The introduction of a gyro introduces an additional electrical complication.

OBITUARIES

Mr. C. S. Middlemiss, C.I.E., F.R.S.

WITH the death on June 11, 1945, at Tunbridg Wells, at the age of eighty-five, of Mr. Charle Stewart Middlemiss, Indian geology has lost its doyen one who will long be regarded as one of the grea figures of Indian geology. Middlemiss was the so of Robert Middlemiss of Hull, where he was bor on November 22, 1859. He was educated at Caisto and St. John's College, Cambridge, taking his B.A degree in 1881. He joined the Geological Surve of India on September 20, 1883, when H. B. Medlicott was still head of the Department.

During his service, Middlemiss did field work i the Himalaya, the Salt Range, and Hazara, all i north-western India ; in Coimbatore, Salem and th Vizagapatan Hill Tracts in the Madras Presidency in the Southern Shan States and Karenni in Burma in Central India, Rajputana and North Bomba (Idar) ; and finally in Kashmir. He also investigate the earthquakes of Bengal (1885), Kangra (1905) and Calcutta (1906). During spells at headquarter he was curator of the Geological Museum (1898–99) and in charge of the headquarters office (1907–8) He was promoted deputy superintendent in 188 and superintendent in 1895. He officiated as directo for two periods, during 1914–15 and in 1916. In 1903 he paid a visit to Ceylon on deputation.

Middlemiss should have retired from the Geological Survey of India on reaching the age of fifty five in 1914, but on account of the War his servic was extended so that he did not leave the Departmen until April 1, 1917, after being gazetted C.I.E. i 1916. As a result of this extension, Middlemis holds the record for length of service in the Geological Survey, amounting to 33 years 6 months an 11 days (beating Medlicott by five months and eigh days). Having created this record, Middlemiss the entered the service of the Maharaja of Kashmir, with the title of superintendent, Mineral Survey, Jamm and Kashmir, from which he did not retire until hi seventy-first year in 1930, after a total service i India of more than forty-six years.

Of other scientific activities, we may record tha Middlemiss became an ordinary and life member o the Asiatic Society of Bengal in 1884, and a fellow in 1912, being at the time of his death the senio member of the Society by four years and also th senior fellow. He became a fellow of the Geologica Society of London in 1900, and was awarded th Lyell Medal in 1914. Middlemiss was elected fellow of the Royal Society in 1921. He was presiden of the Geological Section of the Fourth India Science Congress at Bangalore in 1917 and presiden of the Ninth Indian Science Congress at Madras i 1922. He was also president of the Mining an Geological Institute of India in 1928.

Middlemiss married Martha Frances Wheeler daughter of Major-General Wheeler, of the Benga Staff Corps. They had five sons and one daughter of whom two sons died early in India, and two son lost their lives in the War of 1914–18, in Gallipol and France respectively. On retiring from India Middlemiss settled down at Crowborough in Sussex where he became a centre of local activities. Mr Middlemiss died in 1931.

Middlemiss, as first known to my contemporarie and me, was already in the forties—partially bal with an aureole of grey hair, bright blue eyes, pleasan riendly expression, very sturdily built, and above medium height. He had an extraordinarily youthful mind and was always ready for fun.

This youthful mind was also an experimental one, o that Middlemiss was willing to try anything, and specially anything new. He developed thus a multitude of interests outside geology, the principal f which were perhaps music and sketching in water colours; but he was also interested in verse, n Esperanto, in chess, rowing and lawn tennis. In Esperanto he kept the Calcutta Esperanto Society live, acting as its honorary secretary for some years. n music he devised a new system of notation, not eing satisfied with the existing system. To his unior officers he was very helpful, both in the field nd at headquarters, and because of his friendly ature he was always accessible.

Middlemiss was essentially a field man, believing n the direct appeal to the rocks by means of the ammer. He was able to illustrate his notes with is skilful pencil and brush, often making use also f the *camera lucida* in order to ensure correct outnes in panoramic views; and as in addition he had n accurate but eloquent pen, he has been able to resent the results of his studies in a large number f papers, four of which rank as memoirs, almost all f which contain inspired passages, and all of which mply repay study.

His field work may be divided into three spells, he first of some ten years in north-western India Garhwal, Kumaon, the Salt Range, and Hazara), he second of some twenty-two years in Peninsular ndia (with many interruptions), and the third of ome twenty-two years in Kashmir and Jammu, he latter overlapping his middle period.

Middlemiss's most important work was probably hat done in his first spell, represented by several hort papers and two fine memoirs. In the earlier memoir (*Mem. Geol. Surv. India*, **24**, pt. 2; 1890) he ublished his classic studies of the Siwalik zones of he Sub-Himalaya, and discussed the origin of the Himalaya ranges, adopting Osmond Fisher's views nd showing himself to be an isostasist before the ord 'isostasy' had reached him. In his second memoir (*Mem. Geol. Surv. India*, **26**; 1896), Middlemiss describes the geology of four parallel zones of isturbance or elongated blocks of formations, elonging to the Hindu Kush system of ranges triking north-east, contemporaneous in age with the Himalayan system of ranges striking north-west. s in Garhwal and Kumaon, he shows that as one moves outwards from mountain to plains across these ones each successive outer zone is separated from he preceding inner zone by a major thrust-plane, o that the inner older zone overrides the younger uter zone.

In his brief spell in the Salt Range, Middlemiss arted the controversy not yet ended, as the recent olumns of *Nature* have shown, concerning the age f the Saline series. For Middlemiss cast doubt upon he view that the Salt Marl was Cambrian or pre-Cambrian, as seemed likely in view of the position f this series at the foot of the Salt Range scarp. his he did by demonstrating that everywhere the alt Marl showed discordant relations, often of an pparently intrusive nature, to the physically overing rocks (*Rec. Geol. Surv. India*, **24**, 19; 1891), and explain these phenomena he propounds his hypoesis of the quasi-intrusive nature of the Salt arl (in late Tertiary times).

In his latest contribution, written in his eighty-fifth year (see the symposium arranged by Prof. B. Sahni, *Proc. Nat. Acad. Sci. India*, **14**, Sect. B, p. 267; 1944), Middlemiss claims that his theory of the quasi-intrusive nature of the Salt Marl is in harmony with modern requirements "even though acceptance of the possible guess . . . that an igneous magma may have been ultimately responsible, is too much to expect".

We must now refer to Middlemiss's middle period of work, that in Peninsular India. Here his earlier work was on the magnesite and corundum deposits of the Salem and Coimbatore districts, followed by mapping in the Vizagapatan Hill Tracts, a country of longitudinal strips of acid gneisses, of the charnockite series, and of the khondalite series. Here he found interesting hybrid rocks containing sapphirine (until then only known in Greenland), spinel, cordierite and sillimanite, formed at the intrusive contact of an ultra-basic member of the charnockite series with the sedimentary khondalite series (see *Rec. Geol. Surv. India*, **31**, 38; 1904; and **36**, 1; 1906). He also found nepheline-syenites (miaskite) similar to the rocks of the Urals and Sivamalai in southern India. Later he held charge of the Central India and Bombay party of the Geological Survey of India and produced a detailed memoir on the geology of Idar State (*Mem. Geol. Surv. India*, **44**, pt. 1; 1921).

We come now to Middlemiss's third period—Kashmir with Jammu. Here his first task was to study a recently discovered occurrence of Gondwana plants (*Gangamopteris*) in their stratigraphical relationships. In crossing the Pir Panjal Range by the Golabgarh Pass, he found a supremely important section, with not only *Gangamopteris* but also *Glossopteris* beds overlain in due course by a marine limestone containing *Protoretepora ampla* Lonsd. Middlemiss had thereby succeeded in correlating the great freshwater Gondwana formation of Peninsular India with the richly fossiliferous marine sedimentary systems of the Himalayan area—two widely distinct geological provinces not hitherto found in juxtaposition. The age of the lowest Gondwana beds was shown to be Permo-Carboniferous (Artinskian). His work in Kashmir did not then cease, for he had found incidentally that the previous survey of Kashmir had been made on too small a scale, so that the whole of the geology needed revision. Consequently he set out to make detailed surveys of selected areas and thereby laid successfully the foundations of a new geology of Kashmir, foundations upon which H. S. Bion began to build until his premature death in 1915; foundations upon which Mr. D. N. Wadia built so effectively later that he was awarded by the Geological Society of London in 1943 the same medal as had been bestowed on Middlemiss in 1914, the Lyell Medal.

On joining the Kashmir service in 1917, Middlemiss had to concentrate upon the study of the mineral resources of Jammu and Kashmir. This he did to such effect that he produced no less than ten reports published as *Reports of the Mineral Survey of Jammu and Kashmir*, following two papers published in the *Records of the Geological Survey of India*. Two of these reports deserve mention here. One is his report on the "Bauxite Deposits of Jammu Province" (*Min. Surv. Rep.*, 1; 1928). These deposits are found in association with the Riasi dome of the Great Limestone. The bauxite is of unusual character, being a monohydrate instead of a trihydrate. It is accordingly unusually high in alumina (70–80 per cent instead of 50–60 per cent usual in the lateritic bauxites of the Peninsula); it is also unusually low in iron oxide and of high density and hardness. The quantity is considerable, and one day it will be used, perhaps, with the aid of electric power generated from the high-grade Nummulitic coals that overlie it stratigraphically, or from a projected hydro-electric installation on the Chinat River.

The second paper to be mentioned is on the "Possible Occurrence of Petroleum in Jammu Province" (*Rec. Geol. Surv. India*, 49, 191; 1919), in which he demonstrates the existence of a structure (the Nar-Budhan dome) suitable for the storage of oil, and existing in rocks identical with those of the existing oilfields near Rawalpindi in the Punjab. This dome has not yet been tested. During the course of this latter survey, Middlemiss succeeded in measuring the angle of the thrust-plane or reversed fault (the Great Boundary Fault of the Himalaya) between the Siwalik and Murree zones of formations near Kotli. The angle was found to be only 12°–15°, a much lower figure than had been previously assumed by all who constructed geological sections across the Himalaya, but an angle in accordance with the modern views of *nappe* structure.

This notice is already too long to permit more than a passing reference to Middlemiss's important memoir on "The Kangra Earthquake of April 4, 1906" (*Mem. Geol. Surv. India*, 38, 1; 1910). In this disastrous earthquake more than 20,000 persons lost their lives. Middlemiss shows that there were two epicentral tracts or foci, a principal one in the Kangra Valley of intensity 10 on the Rossi-Forel scale, and a subordinate one in the Dehra Dun of intensity 8 These two foci were situated at the two places where the Sub-Himalayan zone of Tertiary formations embays in a north-easterly direction into the Lower Himalayan zone, and separated by the bulge o bastion of Lower Himalayan formations upon which Simla stands. The earthquake represents, in Middlemiss's view, an attempt to reduce these embayments

L. L. FERMOR.

WE regret to announce the following deaths:

Prof. F. Akerblom, formerly professor of meteorology in the University of Uppsala, on July 24.

Mr. C. E. Fairburn, chief mechanical and electrical engineer of the London, Midland and Scottish Railway, on October 12, aged fifty-eight.

Mr. G. S. Fawcett, managing director of The Tintometer, Ltd., on November 8.

Dr. R. D. Gillespie, the well-known psychiatrist, on October 30, aged forty-eight.

Prof. V. E. Henderson, professor of pharmacology in the University of Toronto, on August 6, aged sixty-eight.

Dr. H. K. Sen, professor of applied chemistry in the University College of Science, Calcutta, during 1920–36, director of the Lac Research Institute Namkum, during 1936–44, lately director of industries Bihar, on June 3, aged fifty-seven.

Prof. C. E. Wright, professor of gunnery and mathematics in the Military College of Science, Woolwich, on October 30, aged fifty-nine.

NEWS and VIEWS

Royal Society Medal Awards

THE King has approved the recommendations made by the Council of the Royal Society for the award of the two Royal Medals for the current year as follows: Prof. J. D. Bernal, professor of physics at Birkbeck College, University of London, for his work on the structure of proteins and other substances by X-ray methods, and for the solution of many other problems requiring a physical approach; Dr. E. J. Salisbury, director of the Royal Botanic Gardens, Kew, for his notable contributions to plant ecology and to the study of the British flora generally.

The following awards of medals have been made by the President and Council of the Royal Society: Copley Medal to Dr. O. T. Avery, emeritus member of the Rockefeller Institute, New York, for his success in introducing chemical methods in the study of immunity against infective diseases; Davy Medal to Prof. Roger Adams, head of the Department of Chemistry, University of Illinois, for his extensive researches in the field of organic chemistry and his recent work in the alkaloid field; Hughes Medal to Prof. B. F. J. Schonland, Carnegie–Price professor of geophysics and director of the Bernard Price Institute of Geophysics in the University of the Witwatersrand, for his distinguished work on atmospheric electricity and of his other physical researches.

Paludrine: a New Anti-malarial Drug

PALUDRINE, or 4888 as it was first called, the new drug for malaria, which was announced at the annual meeting of the Liverpool School of Tropical Medicine on November 5, was discovered in the laboratories o I.C.I. at Blackley, Manchester. The chemical work was directed by Dr. F. H. S. Curd and Dr. F. L Rose, and the biological work by Dr. D. G. Davey The substance has two outstanding points of scientific interest. First, it marks a complete departure in chemical structure from the known antimalaria drugs; it is not a quinoline like quinine and pamaquin, and it is not an acridine like mepacrine—a account of it, together with its constitution, will b given in papers which will appear shortly in th *Annals of Tropical Medicine and Parasitology* Secondly, in avian malaria it has a powerful actio not only on the blood forms of the parasite, but als on the so-called exoerythrocytic forms. The latte are now known to occur in almost every type o avian malaria, and it is the working hypothesis o the I.C.I. group of workers, as it is of some others that these forms also exist in human malaria althoug they have never been demonstrated microscopically

According to this hypothesis, the two major problems of malarial chemotherapy, namely, complet protection against benign tertian malaria by th prophylactic use of drugs, and a radical cur of benign tertian malaria, will be solved b the discovery of drugs with an action on ex erythrocytic forms. Paludrine has such an actio on these forms in avian malaria, and there is som evidence, admittedly very incomplete, that unlik quinine and mepacrine, it acts upon the as yet un demonstrated exoerythrocytic forms of *Plasmodiu vivax* and consequently that it gives a better pr tective action. The investigation is still proceedin

The workers at the Liverpool School of Tropical Medicine, under the direction of Prof. B. G. Maegraith and Dr. A. R. D. Adams, R.A.M.C. officers at Colchester and Woolwich, and Major-General Covell in ndia, are studying the effect of paludrine on the relapse-rate of benign tertian malaria, while in Australia a team of research workers in the Australian Army, led by Brigadier N. H. Fairley, is making an intensive study of its prophylactic action. The work of Brigadier Fairley is noteworthy for the great use which is made of volunteers, and the consequent igorous control which is kept over all aspects of the experiments.

The full significance of all the work, which has been done under the auspices of the Medical Research Council, has still to be assessed, but paludrine appears to be a notable advance in the chemotherapy of malaria. The Liverpool workers, who were the first to treat human cases with the new substance, are impressed by the latitude allowed the clinician in treatment, for doses fifteen or twenty times the size of those necessary to control clinical symptoms can be given with impunity, while Brigadier Fairley is mpressed by the remarkable suppressive action which the drug possesses. Unlike mepacrine, paludrine is not coloured and does not stain the skin. It is also a simpler substance, chemically, and it should be easier to manufacture. The two qualities, potential cheapness and freedom from undesirable effects at therapeutic doses, are themselves sufficient to make paludrine an important new drug.

Government Support for Research Associations in Britain

Announcing in an address to the Conference of Industrial Research Associations on November 6 that grants to such associations would form a permanent part of the activities of the Department of Scientific and Industrial Research, Mr. Herbert Morrison, Lord President of the Council, declared that we need esearch workers to-day as much as in 1940, and that he Government will do everything possible to encourage British industry to use scientific research. It is essential that some of the money gained to ndustry by relief from taxation in the new Budget should be invested in research. Large concerns, he hoped, would establish or extend their own research departments, but smaller concerns should give their full support to existing research associations, for no ingle section of industry can do without this essential scientific partnership and remain virile. Moreover, Government support of industrial research must be backed by readiness to use its results, and firms which cannot maintain fully equipped research taffs of their own should employ at least some trained scientific workers who can co-operate with he appropriate research association and help in the interpretation and application of its work.

Expenditure on research should be regarded as an essential cost, and dealing with the finance of research associations, Mr. Morrison said that with larger incomes the research associations would be able to carry out more of the expensive development work. The Government has therefore decided that in suitable ases it will make single grants to finance capital expenditure for such special purposes as buildings and re-equipment, the purchase of particularly expensive apparatus or the provision of semi-scale plant. Until research association attains an appropriate scale, the present system of a block grant and an additional grant will continue. Eventually, the additional grant will cease, but a new block grant will be made, to continue indefinitely so long as the Department of Scientific and Industrial Research is satisfied with the activities of the association. The associations, Mr. Morrison said, can rely on the Government to proceed as rapidly as possible with the release and training of promising research workers, and all possible assistance will be given for rebuilding or extending laboratories. Sir Edward Appleton, referring to the importance of first-class research workers, pointed out that a monastic life is not stimulating to the young scientific worker, and there should be the closest contact between the research associations themselves, and with the universities and other research establishments.

Air Speed Record by Jet Propelled Aircraft

Group Captain H. J. Wilson, R.A.F., piloting a Gloster Meteor aircraft powered with two Rolls Derwent gas turbine engines, regained the speed record for Great Britain on November 7, flying over a course in the Thames estuary off Herne Bay. The officially recognized speed, being the average of four flights over the course in opposite directions, was 606·2 miles an hour. Mr. Eric Greenwood, the chief test pilot of the Gloster Aircraft Co., also flew a similar course, on another machine of the same type, averaging 603 miles per hour. The previous speed record was held for Germany by Fritz Wendel. This was set up on April 27, 1939, when he flew a Messerschmidt Bs.109R monoplane at 469·2 miles per hour.

The development of the Gloster machine is the result of research and experiment principally by Air Commodore F. Whittle in conjunction with Messrs. Power Jets, Ltd. The final design and construction of the aircraft and the engine were the responsibility of the Gloster Aircraft Co. and Messrs. Rolls Royce respectively. The attainment of such speeds is due to developments that are perhaps less obvious than the actual result. The production of a gas turbine having a thrust at the jet that gives, at 600 m.p.h., a horse-power of from two to three times greater than anything reached by the conventional aero engine is the most important factor. The use of jet propulsion allows this power to be turned into useful thrust more certainly than the usual airscrew method of propulsion could have accomplished. The problems of control of the aircraft at speeds approaching the speed of sound were unique and have been overcome by the aircraft designer. The machine was designed for lower speeds with earlier and less powerful engines, and it is a tribute to his foresight that it has been able to stand up to the increased stresses with a minimum of local strengthening involving no radical redesigning. The actual record-breaking aircraft was a production type of the standard R.A.F. Meteor that is now in service, and has been used in operations both over Germany and for shooting down flying bombs over Great Britain. Special preparation of the machine and the development of the general flying technique for the attempt has been under the supervision of Group Captain Wilson at Manston Aerodrome.

International Council for the Exploration of the Sea

At a meeting held in Copenhagen during October 15–19, attended by delegates and experts from Great Britain, France, Norway, Denmark, Sweden, Finland, Holland and Iceland, the International Council for the Exploration of the Sea was formally reconstituted for a five-year period, as from July 22, 1945. Though the last five-year period ended in 1941, the Council was kept in being throughout the War thanks to the efforts of its president, Dr. Johan Hjort, aided by financial contributions from several Continental countries, including substantial additional subsidies from Denmark. At the recent meeting Dr. Hjort (Norway) was re-elected president, and the following four vice-presidents were appointed to constitute, with the president, the Bureau or Executive Committee: Mr. A. T. A. Dobson (Great Britain), Prof. Martin Knudsen (Denmark), Dr. K. A. Andersson (Sweden) and M. Pierre Tissier (France). Dr. H. Blegvad (Denmark) was appointed general secretary in succession to the late Capt. Nellemose, who fell a victim to the Nazis. The scientific work of the Council is organized by a number of area committees, which draw up co-operative programmes of research that are reviewed by the Consultative Committee. The great majority of these committees were re-established at the recent meeting and agreement reached as to the lines of work to be pursued for the ensuing year. Dr. E. S. Russell (Great Britain) was reappointed chairman of the Consultative Committee.

The Council, which was formally founded in 1902 and, through the courtesy of the Danish Government, has its headquarters near Copenhagen, has now survived two wars and has proved itself one of the most successful organizations set up to co-ordinate scientific research on an international basis. It concerns itself primarily with the investigation of fishery problems, together with the cognate problems of marine biology and hydrography. It has published a long series of scientific reports and valuable annual summaries of fishery statistics and hydrographical data. Its journal, suspended during the War, will, it is hoped, reappear early next year. The recent meeting was well attended, especially by Scandinavian members. The British delegates were Mr. A. T. A. Dobson and Mr. J. E. de Watteville, the fisheries secretaries for England and Scotland, respectively, and the British delegation included Sir John Edgell, lately hydrographer to the Navy.

Nicolas Lemery (1645–1715)

AMONG the students of medicine and pharmacy who did good work during what has been called "the dawn of scientific chemistry" was the Frenchman Nicolas Lemery, the tercentenary of whose birth falls on November 17. He was born at Rouen, and as a youth he spent some years with Glazer at the Jardin du Roi in Paris, but found his master much imbued with the dreams of the alchemists. Proceeding to the University of Montpelier, he spent three years studying medicine, pharmacy and natural history, and then after travelling through various parts of France took up his residence in Paris. By his lectures he gained a wide reputation which was much enhanced by the publication in 1675 of his "Cours de Chymie", which in eighty years went through thirteen editions and was translated into Latin, German, Italian, Spanish and English. Scarcely had he sprung into fame than, through being a Calvinist, he found himself threatened by persecution and, like many of his countrymen, fled to England. Embracing Catholicism, however, he was enabled to return to France and resume his lecturing, and in 1699 was elected a member of the Royal Academy of Sciences. Among his other writings were his "Pharmacopée universelle" and his "Traité universel des drogues simple", both published in 1697. "Chemistry," he said, "is a science of observation, it can only be based on what is palpable and demonstrative." Thom Thomson wrote of him that he was "The first Frenc man who completely stripped chemistry of i mysticism,' and presented it to the world in all i native simplicity". Lemery died in Paris on June 1 1715, leaving a son, Louis (1677–1743), who he important medical appointments in the Frenc capital and published several books.

Karel Vrba (1845–1922)

PROMINENT among men of science in Bohemi towards the end of last century was Karel Vrb Born at Klatovy in west Bohemia on November 1 1845, he studied science at Prague and graduate in 1868, first becoming assistant to the professor mineralogy, Dr. V. von Zepharovich, and later *doce* in petrography. Then he was appointed profess of mineralogy at Czernowitz in Bukovina, returnin to Prague in the same capacity in 1881 when t Czech University was reinstated. At this time the was a complete overhauling of the old collection minerals, to which Vrba constantly added more make it as complete and representative as possibl He gave the first detailed descriptions (sometimes long monographs) of twenty-nine minerals, most occurring locally though a few came from abroa including one from Bolivia. The accounts of stepha ite (1895) and the beryls of Pisek (1888) are regard as Czech classics in science.

For teaching purposes, Vrba constructed speci crystal models that were produced in tens of thousand and were used in all parts of the world, althou their origin was not always attributed to him. H was prominent in the movement that led to t foundation of the Czech Academy of Science in 189 Since 1869 there had been a Natural Science Clu in Prague, and Vrba attended the lectures and join in the biological and geological excursions. Neve theless there was a need for a more august body f the discussion and publication of original research The Academy soon became the leading Czech scie tific institution. Vrba retired in 1912 and liv through the First World War to see the early years the Czechoslovak Republic, though he was too infir to take an active part in the rapid expansion scientific activities that occurred after 1918. Besid other foreign connexions, he was an honorary memb of the Leningrad and Odessa scientific societies.

Announcements

THE following have been elected honorary membe of the Institution of Civil Engineers: Field Marsh the Hon. Sir Harold Alexander and Sir Edwa Appleton.

SIR LAWRENCE BRAGG is visiting Portugal und the auspices of the British Council to lecture "Some Problems of the Metallic State" and on matte connected with X-rays. He will lecture in Lisbo Oporto and probably also Coimbra.

SIR GEORGE STAPLEDON is to retire from the po of director of the Grassland Improvement Stati on December 31. Sir George undertook to organi and direct the work of the Station as a war-ti task, and now wishes to be relieved of these respo sibilities.

AN exhibition is being arranged at the Cur Museum, Alton, Hants, during January 11, 12 and 1 1946, to commemorate the bicentenary of Willi Curtis (1746–99), founder of *Curtis's Botanical Mag zine*, who was born at Alton.

Conditions for the Vernal Increase in the Phytoplankton and a Supposed Lag in the Process

In his recent discussion of the fertility of ocean waters, Harvey[1] mentions that "A phenomenon which seems to lack explanation is the time at which phytoplankton start to increase rapidly at the beginning of he year", for by mid-winter all the known nutrient salts have been regenerated and, in spite of the bright ight of spring, the steep increase in the phytoplankton, as shown by the decrease in phosphate, becomes apparent in the English Channel normally only between March and April, and even much later elsewhere. He mentions the well-known effect of turbulence in carrying the cells down into regions of ow illumination, and suggests that there are unrecognized factors controlling the inception of growth n some areas. Sverdrup[2] also states: "This conditioning of the water may well be a factor in the nitial outburst of phytoplankton growth when other conditions are optimum"; thus he also alludes to an unknown factor.

In 1923 I obtained decisive evidence that light alone is necessary for the full development of the phytoplankton up to complete exhaustion of the phosphate supply[3]. This was done by taking water from the surface of the English Channel about 15 km. out to sea on December 18, 1922, January 16, February 12 and March 8, 1923. These samples were exposed side by side in a south window from March 24 after storing in the dark. It took thirty days to exhaust the phosphate in the December sample, slightly less in the January one and only about five days for the February and March samples. The explanation offered was that the spring samples contained a larger number of cells. "In winter, however, he much smaller numbers present can apparently be doubled or quadrupled with but little effect upon the amount of phosphate as ascertained by analysis."

A culture of the diatom *Nitzschia closterium* W.Sm. showed that half a milligram of phosphorus produced 10^9 diatoms, so this number must be present per cubic metre before any diminution in phosphate can possibly be detected, as 0·5 mgm./m.³ is the limit of sensitivity. The lag in production follows as a mathematical necessity, since in winter the number of plankton cells is relatively much reduced. Using a north window culture of the diatom, it was ascertained that a fourfold increase required sixteen days, March 27–April 13. Thus one cell would, after eight uccessive doublings, become 256 and the process would require 64 days, and similarly for any other rate of increase.

Where vertical mixing is reduced one may find the spring outburst well under way even by February 21, as in the middle of the Channel in 1928; the surface water contained only 5 mgm./m.³ of phosphorus[4], though near the Eddystone and off Ushant there was more than double as much, as also in mid-Channel from 5 metres down. The stability f the water column is thus of fundamental importance, and as already shown[5] the thermal stability of sea water is much greater than that of fresh water, which has maximum density at 4° C. as against − 2° C. for sea water. For the same temperature difference, resistance to mixing increases as the temperature rises. Oceanographers appear to have overlooked these two factors.

Dr. Harvey kindly showed me his proofs in 1943 during my temporary return to Plymouth, and I regret that I did not then direct his attention to the early work. Dr. Harvey still considers that "there is a reasonable *suspicion* that something else besides light, turbulence and grazing plays a part".

Energy of the Hg—C Bond and the Heat of Atomization of Carbon

It has not yet been possible to make a final choice, from spectroscopic and vapour pressure data, between the two alternative values of 124·3 and 170·6 kilo-calories/gram atom for the heat of atomization of carbon ($\Delta H_{291° K.}$ for the change $C_{\text{diamond}} \rightarrow C_{\text{gas}}$)[1], though the most recent treatment favours the higher value[2], and this also makes easier the correlation of some kinetic and thermochemical data[3].

An argument in support of the higher value may be got from the energy of the Hg—C link. The heats of combustion of mercury dimethyl, diethyl and diphenyl in their standard states at constant pressure are 432, 735 and 1,565 k.cal./gm. mol. respectively[4]. These values may be analysed with the help of the following data: heats of atomization (k.cal./gm. atom) C 124·3; H 51·7[5]; Hg 14·6[6]; associated bond energy terms (k.cal./gm. mol. C—C 58·6[7]; C=C 100[8]; C—H 87·3 [7]; benzene nucleus resonance energy 39 k.cal./gm. mol.[9]; latent heats for the phase changes (standard state to gas) $HgMe_2$ 8, $HgEt_2$ 9, $Hg(C_6H_5)_2$ 23 k.cal./gm. mol.[10]. The energies so obtained for the Hg—C bond are: from the dimethyl 1·5, from the diethyl 6·5, and from the diphenyl 3·5: mean 4 k.cal./gm. mol. Even though the energy needed to break the first C—Hg bond is probably greater by about 30 per cent than the mean value for the two bonds[11], 4 k.cal./gm. mol. is an unprecedentedly low value for a chemical bond, and is of the order of the van der Waals attractions.

If we use the higher value 170·6 for the heat of atomization of carbon (with the corresponding changes in the C—H, C—C, and C=C values) the Hg—C energy is increased by (170·6 − 124·3)/4 = 11·5, and becomes 15·5 (energy necessary to break the first C—Hg bond probably about 20 k.cal./gm. mol.). This seems much more probable; it is still very low, but of the same order as the P—P and As—As bonds (18·9 and 15·1[12]).

That the energy of the Hg—C link is very small is supported by many other facts. For example, the spontaneous decomposition of the dialkyls and (on heating) the cyanide to mercury and hydrocarbon or cyanogen; the abnormally low force constant derived from Krishnamurti's Raman spectrum of mercuric cyanide[13]; this is $1{\cdot}16 \times 10^5$ dynes/cm., probably the lowest yet found for any chemical link (we are indebted to Dr. L. A. Woodward for this calculation). Mercury can also be displaced from its alkyls by a great variety of metals (lithium, sodium, beryllium, magnesium, zinc, cadmium, thallium, tin, antimony, bismuth, tellurium). The common idea of the great stability of the mercury alkyls is derived from their indifference to air and water, which is mainly due to the small affinity of mercury for oxygen. But the value for Hg—C derived from the lower heat of atomization of carbon is so extremely minute that the higher value of 170·6 k.cal./gm. atom seems far more probable.

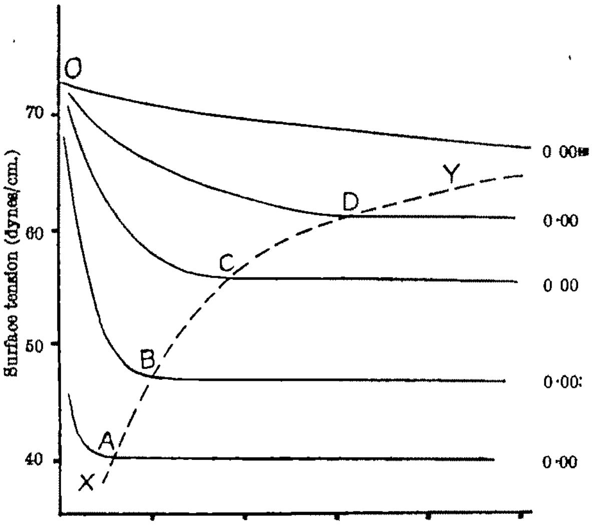
Time Factor in Service Tension Measurement

In recent years various authors[1] have applied static methods to the study of the slow changes which occur in the surface tension of aqueous solutions of some long-chain compounds; and in general the possibility that the accumulation of solute on the surface by diffusion from bulk solution might be responsible for the drift in tension is dismissed on the grounds that the periods of time involved may be as much as 10^9 times greater than those anticipated on classical diffusion theory. My recent quantitative studies of the adsorption process[2] using vibrating jets of aqueous alcohol solutions have confirmed that diffusion to the surface is complete within 10^{-4} to 10^{-1} sec. over the available range of chain-length and concentration, and similar results have been obtained with aqueous solutions of short-chain carboxylic acids. It seems clear that changes in tension over periods of hours, or even days, which occur in solutions of appreciable concentration (and which are usually smaller than the initial fall from the pure water value which occurs during development of the surface layer) are the result of rearrangements in the equilibrium adsorbed layer rather than of diffusion[1].



RELATION BETWEEN SURFACE AGE AND SURFACE TENSION AT 20° C. FOR AQUEOUS SOLUTIONS OF DECOIC ACID AT VARIOUS CONCENTRATIONS.

However, where intermediate time intervals a concerned, I have found that changes in tension du to both diffusion and rearrangement can be observe using the same experimental technique, and in som cases can be clearly distinguished. The time require for the establishment of a surface layer by diffusio diminishes with increasing chain-length, but is extended as the polar nature of the end group, and th dilution of the adsorbate, increase. Suitable combination of these properties can give rise to system in which the forces of diffusion will operate ove periods of time overlapping those employed in th 'slow drift' experiments. The accompanying grap shows the variation in surface tension with tim observed for aqueous solutions of decoic acid a several concentrations. The results were obtaine by a modified drop-weight method, which consiste essentially in the rapid formation of a drop of th solution of predetermined volume on a calibrate orifice, and measuring the time required for th tension to fall to a value equivalent to the dro weight (indicated by the falling away of the drop Full details of this work will be published elsewher

That the curves *OA*, *OB*, *OC* and *OD* represen the development of the surface layer under diffusio forces is supported by the fact that the form of th curves, and the times involved, are of the ord forecast by the general time-adsorption velocit equation deduced from the behaviour of shorter chai systems where diffusion alone can operate[3]. Beyon the points *A*, *B*, *C*, *D* the tension falls very slowl and readjustments in the established surface lay might well be responsible. It appears unlikely th the two factors can overlap, and extrapolation of t appropriate section of the time-tension curve to ze time assists in identifying the type of chan occurring.

In view of the existence of such systems, it is n possible to determine which factor is responsible f the change of surface tension by reference to t order of time alone, and it appears that the terminology, and in particular the expression 'time 'reach equilibrium' in common use in these studie requires some amplification. It is suggested that t use of both the terms 'dynamic surface' and 'dynamic surface tension' be restricted to those surfaces to which solute is in the process of diffusing. When this process is complete, the surface can conveniently be said to have reached dynamic or diffusion equilibrium. All older surfaces would then be termed static, and would reach static equilibrium only after rearrangements in the surface film were complete. The broken line XY in the graph thus traces the variation of diffusion equilibrium with concentration, and represents the boundary between static and dynamic tensions. Methods of measuring surface tension are classified by common usage as static or dynamic, and it is of interest from the above results that static (as well as dynamic) methods are capable of yielding both static and dynamic tensions.

3 : 4-Benzpyrene from Coal Tar

THE extraction of the carcinogenic hydrocarbon 3 : 4-benzpyrene from coal tar, whether by the original method of Cook, Hewett and Hieger[1] (using repeated fractional distillation, extraction with solvents, formation of picrates, and crystallizations) or by Winterstein's modification[2] (involving chromatography), is generally considered too laborious, and the yields obtained too low, to serve as a practical measure for routine supplies. Hence the use of synthetic 3 : 4-benzpyrene for most experimental needs. When it was found[3], however, by a spectrographic method of estimation, that tar might contain as much as 1·5 per cent of benzpyrene, a re-investigation of the methods of isolating the hydrocarbon from tar seemed desirable.

Advantage was taken of the fact that sulphonation of benzpyrene does not readily occur with sulphuric acid alone in the cold, yet the hydrocarbon disappears completely from a solution on shaking with sulphuric acid. The expectation that the benzpyrene would be recoverable from the sulphuric acid washings (by dilution with water and re-extraction with an organic solvent) was confirmed; moreover, a quantitative test with pure benzpyrene yielded almost 100 per cent recovery. Its applicability as a means of isolating the hydrocarbon from tar seemed promising, since most other constituents of tar are either sulphonated by treatment with sulphuric acid in the cold, or else are left unextracted (the latter being the case, for example, with chrysene, and partly with pyrene).

Though the method was not practicable when applied directly to whole tar, owing to the very large amounts of sulphonated material obtained, it proved effective when tried on one of the crude distillation fractions of tar, obtained at 200–240° C. at a pressure of 0·1 mm. mercury (Hyvac and mercury pump), the fraction representing about 10 per cent of the original tar, and containing 2·4 per cent of benzpyrene (as estimated spectrographically).

10 gm. of this material in 100 ml. benzene was added to excess of petroleum ether, filtered, and the filtrate treated (at about 3° C.) with four successive lots of concentrated sulphuric acid. The pooled acid extracts were diluted with water, and extracted twice with benzene. The benzene extract was washed with dilute alkali, dried with anhydrous sodium sulphate, mixed with twice its volume of petroleum ether, and passed through a column of alumina (B.D.H.). The column was then developed with a benzene-petroleum ether mixture (1 : 2), and the early (non-crystallizable) eluates were discarded; the later eluates were collected, evaporated and several times recrystallized (from methanol and from petroleum ether). This yielded 75 mgm of a pale yellow crystalline product, possessing the characteristic fluorescence spectrum of 3 : 4-benzpyrene, and the following m.p. values:

Crystalline product from tar m.p. 171–173° C.
Synthetic sample for comparison m.p. 175–176·5° C.
Mixed m.p. 171·5–173·5° C.

The yield of 75 mgm. of almost pure benzpyrene from 10 gm. of a crude distillate of tar, by a relatively simple procedure, seems sufficiently promising for application of the method on a large scale as a practical means for supplying this important hydrocarbon.

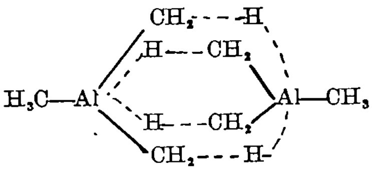
Aluminium Trimethyl

IN a recent letter, Burawoy[1] remarked that the ethane-like structure ascribed by us[2] to the dimeric form of aluminium trimethyl from electron diffraction investigations, and supported by Brockway and Davidson[3], is most unlikely. He proposed an alternative.

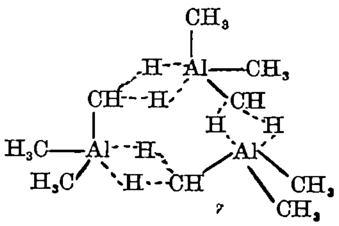
This method of examination does not enable us to deduce structures for such complicated molecules. They must be invented and tried; and for such a case, especially when not many orders of diffraction can be observed, it is impossible to say that any one satisfactory solution is unique. We have therefore tried Burawoy's model, and a number of others which we devised on various hypotheses about the type of binding without regard to their probability, for it is clear that the binding, whatever it is, must be new in some degree. We entertained the possibility that the degree of polymerization is more than two[4].

Burawoy's model proves unsatisfactory in both the qualitative and the quantitative fit of the simplified theoretical scattering curve with the observed scattering. We have, however, found three other more or less satisfactory models: I is a cage-type structure for the dimer; II is a ring structure for the trimer; III is a ring structure for the dimer with the ring not perpendicular to the plane of the other atoms. I is very good, II is quite good, III is fair. It may be recalled, also, that Brockway and Davidson rejected one of the ring models for the dimer (the sixth which they tried) more because it seemed improbable than because its scattering curve is bad. At present the experimental evidence available does not suffice for a definite choice between these possibilities to be made.



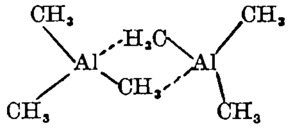
Model I

Al-C = 2·01; C-H = 1·09; Al..Al = 3·34, Al..C (ring) = 3·23 A.; ∠C-Al-C (ring) = 138°; ∠C-Al-C = 111°, C..H, Al..H not specified.



Model II

Al-C = 2·05; C-H = 1·09; Al..C (bridge) = 2·05; Al..H = 1·85; C..H = 1·30 A.; ∠s tetrahedral.



Model III

Al..Al = 3·20; Al-C = 2·05; Al..CH_3 = 2·59 A.: ∠C-Al-C tetrahedral throughout.

The structures which appear to do least violence to current theory are I and III. These could arise if the association were due primarily to polar character in the Al-CH_3 bonds (the methyl groups being negative). The attraction may be increased by some polarization of the methyl groups by the aluminium atoms which they approach.

A fuller account of the calculations and of the theoretical considerations will be given elsewhere.

Concentration of Solutions of Salts of Penicillin

PENICILLIN as a chemotherapeutic agent is usually employed in the form of its sodium or calcium salt: a concentrated solution of one of these salts is used for parenteral injection or for local application. For the latter form of treatment penicillin in solid form is often used (usually the calcium salt). Owing to the instability of solutions of these salts of penicillin it is necessary to prepare and store the salts in the solid form and to dissolve in the appropriate volume of water or saline shortly before required.

In order to obtain salts of penicillin in the solid form, evaporation *in vacuo* of the concentrated solutions at low temperature is necessary, and the lyophilic drying process, in which evaporation takes place from the frozen state, has been the method of choice. The lyophilic drying process is, however, very slow, especially with the apparatus usually available in the laboratory, and it is therefore desirable to concentrate the solution as much as possible before drying.

This concentration may be achieved by extraction of the free penicillin at pH 2 with organic solvents, the salt being formed from the extract by treatment with the appropriate alkali and a smaller volume (for example, one tenth) of water[1,2,3]. This method of concentration may be repeated if necessary, yielding very highly concentrated solutions of the salt.

At alternative method of concentration which has advantages over that outlined above has been developed as the result of an observation made during the preparation of penicillin in these laboratories. Thus, it was noticed that frozen solutions of the sodium salt of penicillin when allowed to thaw at room temperature gave fractions varying in composition (for example, in pigmentation)[3]. The process has now been examined in more detail, and the 'drip-thaw' method, as used by McFarlane for fractionation of blood plasma[4], has been found suitable for concentrating solutions of the salts of penicillin. Preliminary experiments showed that penicillin potency could be correlated with the degree of pigmentation, and the volume of the respective fractions was determined by observing, as thawing proceeded, the progressive decrease in the colour of the drops of fluid. Satisfactory results were finally obtained by fractionating into three fractions.

Thus, in a typical experiment, a solution of the sodium salt of penicillin (400 c.c.) was frozen at −25° C. and the bottle containing the frozen solution was inverted and allowed to 'drip thaw' at room temperature. Three fractions were collected and there was a progressive variation in penicillin content, pigmentation and alkalinity. Assay tests showed that about 90 per cent of the penicillin content of the original solution was concentrated in the first fraction, which was highly coloured and about half the original volume; the second fraction, which was only pale yellow in colour, contained most of the small amount of penicillin remaining, while the third fraction (colourless and about one fifth of the original volume) contained less than 1 per cent of the penicillin content of the original solution.

By this process solutions of the sodium salt of penicillin with a potency, for example, of about 3,000 units per ml. may be fractionated to yield a first fraction with a potency of 5,000 units or more per ml., that is, to a potency suitable for parenteral injection.

Since the bulk of the penicillin content of the original solution is concentrated in the first fraction, the volume of solution for lyophilic drying is reduced to about a half. The fractional thawing may be repeated on the first fraction, for example, thus still further reducing the volume of solution for lyophilic drying. In one or two instances the lyophilic drying process has been omitted, and solutions of the sodium salt of penicillin have been concentrated to a high potency by the above method, and have been stored for several weeks in the frozen state without appreciable loss of potency.

Assay tests on the fractions have shown that, as would be expected, there is practically no loss of penicillin; the process is easily carried out, requiring little attention, may readily be accomplished under aseptic conditions, and is, in fact, ideal for the concentration of solutions of unstable substances such as the salts of penicillin.

The method is suitable for the concentration of solutions of the calcium salt of penicillin, and it may o be of value for the concentration of solutions other antibiotics or of antibacterial substances.

We wish to thank Dr. C. P. Stewart, of the Blood ansfusion Service, Royal Infirmary, Edinburgh, providing facilities for the freezing of the solutions penicillin used in this work.

xual Differentiation of the Gonad and the Sexualization of the Germ Cells in Teleosts

In the Amphibia and Amniota, the original exuality of the gonad is evident from the dual gin of its two main constituents—the *cortex* from e peritoneal wall, and the *medulla* from the interal blastema[1]. Sexualization of the germ cells, ich are originally indifferent, results from the action one or other of the sexual differentiators which produced in these areas, *medullarin* inducing aleness and *cortexin* femaleness (Witschi).

With this in view, several authors (Essenberg, ldine, Dantschakoff, Lepori) have tried to identify rtical and medullary regions in the gonads of leosts. My own observations on several species do t support such a double origin, and a critical examation of the literature leads me to believe that in e Teleosts generally (as judged from the species idied to date) the somatic substratum of the gonad s a simple origin from the peritoneal wall.

In the Teleosts, as in the Cyclostomes[2], the germ lls do not at first exhibit male and female characterics, which appear later in development. The mordial germ cells or *protogonia* (Beccari) multiply a certain number of generations, giving rise to lls which I call *deutogonia*, becoming separated from ch other or temporarily united into small groups. ese are always sexually undifferentiated. The nale cells first become recognizable oocytes during maturative prophase and during the processes of owth and deutoplasmogenesis ; the male cells first close themselves as such when they multiply to m encysted groups of secondary spermatogonia. e two sexes are thus first distinguishable by the owth and suspension of division on the part of the nale cells, and the continued multiplication within sts of the male elements. Between these two exmes every degree of intermediate condition is to found, giving cells in a state of *intermediate uality*.

Growth, deutoplasmogenesis and meiotic prophase y be initiated in cells which are derived, after a ies of generations, from the early protogonia, but y may also set in immediately in the first generaa of deutogonia, a condition which we have erred to as *abbreviated oogenesis*[3].

We see therefore that the development of the germ ls is characterized by an initial state of indeterminacy, which applies also to the gonad as a whole. This is particularly evident in the eel, and I think is the primitive condition in the Teleosts[4]. In the eel we can trace, from an initial indifferent condition, the progressive sexual orientation of the gonad with an increasing predominance of the germ cells of either male or female type. Parallel with this there is a regression of the heterologous sex elements and the accentuation of the male or female structure of the gonad. In the male these changes are recognizable in the development of the vas deferens and in the cordonal arrangement of the spermatogonia, and in the female in the lamellar arrangement of the oocytes.

The initial state of the gonad, as described above, is one in which the two opposing tendencies are balanced and can be defined as *intersexuality*. According to Goldschmidt[5], the essential difference between intersexuality and hermaphroditism lies in the temporal succession of two opposing tendencies in the first and the co-existence of both in the second. In my opinion, intersexuality is rather characterized by the incompatibility between the two tendencies, and hermaphroditism by their mutual tolerance[6]. This difference is probably due to the diffusible or non-diffusible nature of the sex differentiators.

Among the Teleosts we have a typical example of hermaphroditism in *Sparus auratus*[7]. Here, in the same gonad, the protogonia localized in the marginal ventral portion become differentiated in the male sense, while those distributed along the median and partly along the lateral walls of the central cavity differentiate in the female sense. In this case differentiation of each germ cell proceeds directly in one direction or the other with no intermediate condition of intersexuality. In *Sparus* there is constant *protandry*, that is, the male germ cells mature before the female.

In the Sparidæ there are other species (for example, *Diplodus* spp.) in which the testicular and ovarian areas likewise appear in the same gonad, but only one of them reaches maturity. Here, therefore, we see the transition from hermaphroditism, which must be considered as the primitive condition, to gonochorism.

With *Sparus auratus*, as in all cases of hermaphroditism, there is a genetically determined balance between the two opposing sex potencies. The differentiation in the same individual of male and female gonocytes cannot be interpreted as the direct effect of hereditary factors, but must be regarded as determined by the surrounding somatic tissue. The spatial separation of the protogonia destined to form sperm and ova lead us to believe that the somatic tissues of the gonad are chemodifferentiated into regions producing either male- or female-inducing substances.

Even in the eel, where there is no spatial separation of prospective male and female protogonia, we are led to the same general conclusion. The ultimate sexualization, which takes the form of an increasing predominance of one type of germ cell over the other, must be induced by local influences in the surrounding somatic tissue of the gonad[8].

In the Amphibia this is still more obvious. The protogonia become oogonia if they remain in the cortex of the gonad. If, however, they migrate into the medulla, they become spermatogonia. If migration is incomplete or delayed, the result is a condition of intermediate sexualization[9].

It would thus appear that in the vertebrates generally the germ cells are originally indifferent and later become sexualized under the influence of the somatic substratum of the gonad. This conclusion seems at first sight paradoxical and at variance with the widely held belief in the continuity of the germ plasm. It seems that the sex of the germ cells is not determined by genetic factors passed directly from the zygote through a series of germinal cell generations. But in species with genotypic sex determination, the sex-determining influence appears to pass first to the somatic tissues, which in turn induce the sexualization of the germ cells. In species in which there is a balanced genotypic sexuality (intersexuality), sexualization of the germ cells is likewise probably due to influences originating within the organism or from the external environment and acting always through the somatic substratum of the gonad.

Use of Dibenzylphosphoryl Chloride for Phosphorylations

ABOUT ten years ago, one of us (A. D.), at the suggestion of Dr. P. Eggleton, began experiments on the synthesis of some biologically important phosphorous compounds at the Physiology Department of the University of Edinburgh. In the course of these experiments, the chloride of dibenzylphosphoric acid was prepared and its usefulness proved in preliminary experiments. This work had to be broken off and could not be resumed until recently.

In the meantime, L. Zervas[1] has introduced the silver salt of dibenzylphosphoric acid as a phosphorylating agent; he considers the chloride too unstable for convenient use in phosphorylations.

We find that the chloride, prepared according to our original procedure from the potassium salt of dibenzylphosphoric acid with thionyl chloride in chloroform, is sufficiently stable for preparative use in phosphorylations. Guanidine dibenzylphosphoric acid can easily be prepared by shaking the chloride with a 25 per cent guanidine solution. Within a few minutes the oily chloride disappears and a solid is precipitated. After filtration and washing with water, the crude product is recrystallized from alcohol-ether; m.p. 166·5–167·5° C.; yield 80 per cent. By hydrogenation with a palladium catalyst, guanidinophosphoric acid is obtained. We have prepared a number of substituted amino- and guanidinophosphoric acids and are at the present time occupied with experiments on the phosphorylation of hydroxy-compounds.

When treated with a cold dilute potassium hydroxide solution, dibenzylphosphoryl chloride yields the tetrabenzylester of pyrophosphoric acid in good yield; m.p. 59–60° C. The substance is insoluble in water, soluble in alcohol and ether and decomposes with warm alkali to form dibenz phosphoric acid. Our attempts to prepare tribenz pyrophosphoric acid by partial saponification hydrogenation of the tetrabenzylester have hither been unsuccessful.

Air Photography in the Far East

THE recent article[1] by Wing-Commdr. Hamsha Thomas is very timely. I have recently been attach to H.Q., S.E.A.C., so I have had considerable opp tunity of seeing the part played by air photograp in that region. When the time comes for the f story to be told, it will be found that many of th applications are likely to be those described in th recent article. My present purpose, however, is put on record a plea for the continuation of R.A. air survey in the tropics as well as in England. T need in the Far East is even greater than in Gre Britain, because many of the tracts of country a almost inaccessible. One need scarcely say that th governments concerned, for example, India, Ceylo Malay and Burma, are fully aware of the great val of air survey, but too often decisions are made Great Britain by people who are not familiar wit the needs elsewhere. Here one may refer to the aeri surveys carried out for the forest service in Burm for example, Irrawaddy and Lower Tenassarim, b tween the two Wars, though for present-day purpos these were on a small scale. There has also be great improvement in technique since these survey were carried out, and much of the work must requi repetition.

One or more units of the R.A.F. ought to be mai tained in the Far East and their work made availab to the resident scientific men and government depar ments. In this connexion also it is to be hoped th the vast collection of photographs now accumulat in the Far East will not be destroyed but made ava able in the near future to men of science for stud Finally, there is not only the question of the co tinuance of air survey, but there is also the proble of service photographic research. It is highly desi able that this should be continued, not only in Gre Britain but also in the tropics. Conditions for phot graphy are obviously completely different in th tropics, and we have by no means fully master them. They cannot properly be overcome by sim lating tropical conditions in Britain, and it is mo important that a photographic research unit shou be set up and maintained in either India or Ceylo This unit could operate as an out-station of the ma research centre in Britain. During the course of the investigations, if there is proper co-ordination betwe them and local scientific men and local needs, mu useful work could be done. This type of peace-tim co-ordination is already in evidence at the arm photographic research centre in Wiltshire. It is be hoped that the R.A.F. will follow suit.

ASSOCIATION OF SPECIAL LIBRARIES AND INFORMATION BUREAUX

ANNUAL CONFERENCE

HE twentieth Conference of the Association of Special Libraries and Information Bureaux, held the Portland Hall, Polytechnic Extension Building, ndon, during September 15–16, drew the largest endance of recent years, and the new *venue* proled more of the opportunities for informal dission and contacts which were such a useful feature the residential conferences arranged before the ar. Even at the conversazione at the Royal titute of British Architects on the Friday which ceded the formal opening it was evident that this s appreciated; and there was, further, a clear desire a conference to be held in a northern and industrial tre which afterwards found expression at the nual general meeting and in the discussion which lowed Mr. E. N. Simon's paper, "Some Problems the Special Librarian in Industry". The liveliness the discussion on that paper, like that on Mr. E. J. rter's paper on "The Planning and Equipment of search Libraries and Information Bureaux", inated that the time available was all too inadequate. deed, the general impression was gained that these o sessions, with that at which Miss M. Bateman sented her paper, "Some General Desk Reference oks", the discussion on the book shortage over ich Mr. L. J. F. Brimble presided, and some portunity for informal discussion of the ideas own out by Prof. J. D. Bernal in his opening dress, would have provided more than enough, addition to the formal business, to satisfy the jority of those attending.

n contrast to the usual practice, the Conference ened with the annual general meeting at which report of the year's work was presented. Memberp has risen to 530, and the subscriptions increased £1,500. Grants of £300 from the British Council 1 £1,000 from the Department of Scientific and lustrial Research were received during the year, d the income and expenditure account shows a plus for the year of £241.

nly two Library Training Courses were held durthe year, and the second of these did not end til July 1945. The first issue of the *Journal of cumentation* appeared in July 1945 and nonmber subscribers to the ASLIB Book List now mber 424, including 230 copies distributed through British Council. Preliminary steps have been en towards the compilation of a "Directory of dical Libraries and Sources of Information", and ew edition of the "Select List of Standard British entific and Technical Books" is also in preparation. Publications Committee has also been responsible editing a guide to "British Sources of Informa1", commissioned by the British Council for the of libraries overseas. ASLIB has also collaborated h the Library Association and the National tral Library in compiling a list of American iodicals missing in transit or through enemy on during recent years. This is the first step in heme by which it is hoped that some replacements y be obtainable through co-operation with erican libraries, even when the issues in question out of print.

Following the annual meeting, Prof. J. D. Bernal gave a challenging address on "Information Service as an Essential in the Progress of Science". Dealing primarily with the user's side of library service in relation to research, Prof. Bernal made a strong plea for closer co-operation between the librarian and the research worker and for a fuller understanding of each other's needs and problems. The modern information service should endeavour first to secure that the right information in the right form was sent out to the right people, and, secondly, to arrange that facts of diverse origin which might bear on any particular topic should be correlated for the study of that topic. The very fact that the productive capacity for scientific information increased so greatly, while the absorptive capacity did not increase, accentuated the importance of these distributive and integrative aspects of library service, and Prof. Bernal suggested that in the future the librarian should be master of the material itself and be in a position to present it in forms different from those in which he receives it. It is the librarian's job not merely to accept material as sent to him, but also to demand that the material be presented in the appropriate forms for passing on. This implies a much closer relation between the librarian and the research worker as well as between the function of the librarian and that of the publisher, and Prof. Bernal referred to the way in which war-time experience of the dangers of departmentalism in information service had emphasized the unity of the whole question of scientific communications. It had become clear that, so far as information service for furthering research was concerned, a thorough recasting of the whole system was required, and the present period of rehabilitation offered a unique opportunity for a new start.

The primary unit in scientific communications was the individual scientific paper dealing comprehensively with one topic, and in Prof. Bernal's opinion the scientific journal had ceased to be a really satisfactory means of distributing scientific information. He suggested that the individual scientific paper was the proper basis for distribution as well as for publication. Under the proposed scheme the papers, after being passed for publication by referees, would be forwarded by scientific societies to a national centre which would act as clearing house. The papers would be published in three lengths: in full, possibly as microfilm; in the main, printed; and in summary or abstract. Prof. Bernal visualized a unified abstract service. For indexing, the title of the paper would be sufficient for most purposes. The scientific societies would retain their editorial functions, but it was particularly important that the scheme should be on an international basis from the start, and librarians who were able to appreciate the need for order and uniformity in the presentation and distribution of information should stress to scientific societies and governments the folly of independent action.

At the afternoon session when Sir Frederic Kenyon presided over a symposium on "Links with the U.S.A.", there were some striking omissions. Miss Taylor read a paper by Dr. R. H. Heindel on "The American Library in London" and indicated that this was likely to be retained in some form or other. The arrangement by which H.M. Stationery Office will act as a sales agent for the publications of the U.S. Government Printing Office was also mentioned as likely to operate in the near future, and the paper was supplemented by a list of some guides to American publications. Mr. R. H. Hill read a joint paper with Mr. E. G. Tayler describing the Bureau of American Bibliography established at the National Central Library on January 1, 1938, and the collaboration of the National Central Library with the Committee on International Relations of the American Library Association in the distribution of American books and periodicals to men serving in the British Forces at home and overseas. Mr. W. C. Dalgoutte described the British Information Services in New York and the work of its four divisions—information, including the library, which is the main link between the organization and American libraries; press and radio; general, including speakers and circulation; and films; and he referred to the growing demand for information on Britain's financial and economic position. In a paper on the work of the American and British Commonwealth Association, Major W. E. Sinnett referred to plans for an Anglo-American Library of Reference which were in abeyance with the formation of the American Library under Dr. Heindel, and to the foundation of an Anglo-American Institute of Cultural Relations and Study. Mr. L. R. McColvin outlined cultural relations with the United States organized by the Library Association, and a paper by E. S. Cavanaugh on the work of the Special Libraries Association was read by Miss Ditmas in which the proposal for an Educational and Cultural Organisation of the United Nations was welcomed and reference made to Mr. Archibald MacLeish's plan for inter-library loans on an international basis to help the devastated libraries in Europe.

A paper on exchanges of staff and students between British and American universities, by Mr. R. A. Johnson, appeared singularly out of date. Taken from an article published in October 1944, it omitted all reference to the more recent arrangements such as that between the University of Manchester and the University of Virginia. Among papers presented in person were those of Mrs. Beatrice Warde describing the operations of the "Books Across the Sea" societies and of E. A. Ford on the "Educational Work of the English Speaking Union", but in an overloaded symposium there was little reference to the scientific field and none at all either to the work of the Scientific Offices in Washington or in London or to the important proposals in the recent report of Dr. Vannevar Bush.

By way of contrast, almost the whole of the following session was given over to lively discussion of Mr. E. N. Simon's paper. Possibly Mr. Simon overstressed the need for education inside a company—his own experience on this point was not generally corroborated—but there can be no question as to the importance of more propaganda on the part of ASLIB. The Association has sometimes tended to preach too much to the converted, and Dr. W. H. Brindley's suggestion for more joint or conjoint meetings of ASLIB with the scientific societies and professional associations should be followed up. Mr. Simon himself indicated that the primary task of the information officer is to direct his clients to reading, not to read for them, and in fact the technique of good showmanship is an important part of the equipment of a first-class works librarian as of the public librarian. Mr. Simon gave frank expression to a number of problems, internal and external, with which most librarians are confronted, and succeeded in conveying a point of view that is not always recognized. Not every librarian appreciates the ha
that, is done by automatic reminders or reca
whether or not the borrowed volume is actually
quired for use elsewhere, though, of course, ev
librarian knows that in the absence of a remin
system the book may never come back, whethe
is in use or not. The question of co-operative tran
tions Mr. Simon discussed at some length and a
the functions of ASLIB, and if all his strictures co
not be maintained the plea for a northern confere
received strong support. Such a conference sho
do much to remove the main burden of Mr. Sim
strictures on the Association—that its discussi
are conducted in too general terms, insufficiently
lated to specific problems; and if at the same ti
the suggestion that active steps should be taken
enlighten chambers of commerce, sales manag
associations, bankers, municipal officials and oth
as to the importance and value of information servi
is adopted the steady growth of the industrial me
bership of ASLIB may in itself supply whate
further impetus is required for the movement ur
by Mr. Simon.

Mr. Edward Carter's paper on the planning a
equipment of research libraries and informat
bureaux at the Sunday morning session, over wh
Mr. S. W. Gibson presided, alone would have gi
value to the Conference for the industrialist, but o
again the session was overloaded by bringing
Mr. C. E. A. Bedwell's paper on "Hospital Libr
Accommodation", which not only curtailed the
cussion but was clearly regarded by the majority
those present as extraneous, if indeed it fell prope
within the sphere of ASLIB at all. Mr. Car
emphasized the importance of flexibility of plan a
freedom to expand and suggested accordingly t
the least possible amount of equipment should
fixed. Increase in size inevitably compels chan
in the qualitative elements of a library's organi
tions, including the main plan elements, doorw
and walls as well as equipment, and changes sho
be allowed for, even if they cannot be calculated
detail. Moreover, provision for expansion sho
cover not merely straightforward increase in ho
ings but also increase or intensification of servi
Usually this will mean more staff for whom wo
place must be found, and this is often difficult exc
at the expense of reader-space even if the sou
principle is observed—not, however, mentioned
Mr. Carter—that only those members of the librar
staff actually responsible for service to readers sho
be located in the reading-room itself.

Without dealing in detail with library planning,
Carter indicated his objections to the university t
with reader's bays and emphasized the desirabi
of the librarian's own room being situated where
will be in close contact with both readers and st
On lighting and acoustics he made many import
practical observations, and his comment that it i
important to prevent noisy conditions in ro
where staff are at work on tasks demanding concen
tion as in reading rooms will be appreciated.
pointed out that a sustained background noise
traffic or machinery is generally not troublesome
can even be helpful in muffling foreground distu
ances such as conversation, a squeaky pen and
on. Readers prefer, he finds, to sit facing rat
than alongside each other unless the space betw
adjacent readers is very generous. Something m
than minimum seating comfort is one of the ameni
which any but the poorest research body sh

afford, and all shelving should be adjustable. Mr. Carter's whole paper is packed with observations, notes on minimum standards, and data for calculations for accommodation and design which should be valuable even to the experienced works librarian, and further comments on a number of his points are to be found in S. Rowland Pierce's "Some Notes on the Planning of Research Libraries", who expresses the opinion that where doors are not provided to the bookshelves there should be no books between twelve or eighteen inches of the floor.

There is room for more discussions of the type that followed Miss M. Bateman's paper on "Some General Desk Reference Books" at the afternoon session on September 16, though the speakers betrayed a tendency to think in terms of specific reference books rather than those of a general, all-round usefulness. This session was followed by a discussion on the great book shortage, over which Mr. L. J. F. Brimble presided. This was opened by a paper by Miss E. M. R. Ditmas who, after recapitulating the causes of the shortage, referred to its effects in education and research and its bearing on Empire intercommunications and the re-establishment of cultural relations with Europe. In regard to research, Miss Ditmas quoted figures supplied by the research department of a large firm carrying on research of vital national importance, showing how the position has steadily deteriorated since 1942 and the dependence on American rather than on British books—a dependence which, with the termination of Lend-Lease, may have serious repercussions on industrial and scientific development if books are regarded as articles of luxury or merely a commodity of trade. The immediate demand for British publications is far in advance of the normal pre-war demand, while stocks are at their lowest. The discrepancy between supply and demand grows monthly, but the remedy must take account of labour n both the paper-making and the printing and bookbinding industries as well as transport and materials.

In the lively discussion which followed, Miss Ditmas's remarks in regard to the effect of the book shortage on research was stressed by Dr. V. E. Parke and other speakers, including the chairman, who expressed the opinion that books needed for research and for the universities were more important than hose needed for schools, where the numbers run into hundreds of thousands of volumes. Reference was made to the possible help of the American Library n arranging facilities for inspecting American books which could not be obtained on approval, and the hairman endorsed a deserved tribute paid by Prof. R. S. Hutton to the services of Messrs. H. K. Lewis and Co., Ltd., and other leading booksellers in prouring American literature. Mr. H. L. Jackson, of Messrs. H. K. Lewis and Co., Ltd., thought that Miss Ditmas had given a very good account of the position and that the shortage was most acute in the educational field. Confirming that the labour position rather than the paper shortage* was the most acute difficulty, he suggested that it would be better to send a deputation with a resolution rather than submit a resolution nly from the Conference. After further discussion a resolution was approved suggesting that the Council f the Association of Special Libraries and Information Bureaux should take definite action along such ones, either by a deputation to the Ministry of Labour or other Ministry or by way of resolution.

---

* Since this discussion was held, a fifteen per cent increase in paper location has been announced.

CHEMICAL COMPOSITION OF MARINE ORGANISMS

THE data on the chemical composition of marine organisms are widely scattered; hence Prof. A. P. Vinogradov's paper on "La composition chimique élémentaire des organismes marins" (*Trav. Lab. Biogéochimique, Acad. Sci. URSS.*, Pt. 1, 1937, Pt. 2, 1941, Pt. 3, 1944) is a valuable contribution to our knowledge of the elemental chemical composition of marine plants and animals; it is in Russian. Essentially it represents a compilation of many thousands of elemental analyses of marine organisms, and the bibliography alone, printed in double columns in close type, occupies 44 pages. The data presented are accompanied by extensive critical discussion and comments. Part 1 embraces Algæ, Bacteria, Protozoa, Porifera and Cœlenterata; Part 2, the remaining Invertebrata and a part of a chapter on the chemical composition of respiratory pigments; and this chapter is carried over to Part 3, which also contains additional notes on the composition of Invertebrata, composition of Pisces, composition of skeletal parts of animals, a general summary and special chapters dealing with the problems of geology and evolution from the biogeochemical point of view.

Although the collection of analyses appears to be enormous, its usefulness in its present form is somewhat limited, mainly because the analyses are usually confined to certain chemical elements found in certain parts of organisms (soft parts, skeleton, ash, etc.), and there is no attempt made to evaluate the composition of complete organisms. This means that any attempt to give a generalized view of the chemical composition of individual species is bound to be rather vague, and any comparison between them very difficult. This fault certainly does not lie with the author, whose perseverance in collecting these data is truly remarkable. In spite of these difficulties the author makes an attempt to trace the relation existing between the composition of organisms and the composition of the ocean and to find out the major changes in chemical composition of organisms during geological time.

From the point of view of geology, or rather of biogeochemistry, as this branch of science is now called in the U.S.S.R., an especially important question is that of the concentration of certain chemical elements by marine organisms, which often leads to the deposition of rocks of biogenic origin, such as limestone, diatomite, manganese and iron ores and petroleum. "Marine organisms, concentrating certain elements and dispersing others during the process of their living activity, are performing complex and varied geochemical functions. Their chemical elemental composition, as shown by thousands of analyses, does not appear to be a simple reflection of the chemical composition of the surrounding medium. The varying chemical composition of the organism is determined by their physiological character, which in its turn is produced by lengthy interaction between each organism and its medium. On closer investigation we can discover that the chemical composition of the organism reflects its genetic history." According to the author, each species of organism is characterized by its own chemical composition, which has remained more or less constant throughout geological time, and only new species show a marked change in composition.

S. I. TOMKEIEFF.

FORTHCOMING EVENTS

Monday, November 19

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Dr. F. C. Bawden. "Virus Diseases of Plants", 1 "Symptoms of Virus Diseases" (Cantor Lectures).

Royal Geographical Society (at Kensington Gore, South Kensington, London, S W.7), at 5.30 p.m.—Mr. C. P. Skrine. "Persia and Afghanistan" (Kodachrome films and commentary).

British Institution of Radio Engineers (at the Birmingham Chamber of Commerce, 95 New Street, Birmingham 2), at 6.15 p.m.—Discussion on the Radio Industry Council Report on "Post-War European Broadcasting" (to be opened by Mr. A. H. Cooper).

Tuesday, November 20

Royal Society of Arts, Dominions and Colonies Section (at John Adam Street, Adelphi, London, W C.2), at 1.45 p.m.—Dr. G. Macdonald "Tropical Hygiene and the Overseas Empire".

Royal Institution (at 21 Albemarle Street, London, W.1), at 5.15 p.m.—Dr. Kathleen Lonsdale, F.R S. "Recent Research Work in the Davy Faraday Laboratory" (1) "Atomic Movements in Crystals".

Eugenics Society (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 5 30 p.m.—Dr. A S. Parkes "Some Problems of Reproductive Physiology".

Association for Scientific Photography, Medical Group (at the Hastings Hall, B M A House, Tavistock Square, London, W.C.1), at 6 p.m.—Discussion on "Equipment for Medical Photography". (to be opened by Dr. A. C. Roxburgh and Mr. J. E. Andrews).

Royal Photographic Society, Scientific and Technical Group (at 16 Prince's Gate, London, S.W.7), at 6 p m.—Dr. W. F. Berg: "How it Works in Photography", 2. "Latent-Image Theory without Tears".

Wednesday, November 21

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m —Mr. Henry Berry "The Thames Conservancy".

Institution of Electrical Engineers, Radio Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5 30 p m.—Mr. J. R. Brinkley "A Method of Increasing the Range of V.H.F. Communication Systems by Multi-Carrier Amplitude Modulation".

Institute of Fuel (at the Institution of Mechanical Engineers, Storey's Gate, St. James's Park, London, S.W.1), at 6 p m.—Dr. M. Fishenden and Dr. O. Saunders. "Heat Transmission" (Second paper in the Industrial 'Waste Heat' Recovery Series).

Society of Chemical Industry (at the Royal Institution, Albemarle Street, London, W.1), at 6 15 p m.—Sir Harold Hartley, F.R.S.: The first H. E. Armstrong Memorial Lecture (members of the Plastics Group are particularly invited).

Institute of Welding, Wolverhampton Branch (at the Victoria Hotel, Wolverhampton), at 7 p.m.—Mr. T. E. Calverley. "Electrical Technique in Resistance Welding".

Thursday, November 22

Institute of Physics, London and Home Counties Branch (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 5 p.m —Dr. J. M. Meek and Mr. C. E. R. Bruce. "Some Recent Theories of the Electrical Discharge".

Royal Institution (at 21 Albemarle Street, London, W.1), at 5.15 p.m.—Prof. James Gray, F.R.S: "The Anatomy and Functions of the Brain in Lower Vertebrates" (iv) "Mammals"

Chemical Society (joint meeting with the University College of North Wales Chemical Society) (in the Department of Chemistry, University College, Bangor), at 5 30 p m.—Prof J. W. Cook, F.R.S.: "Colchicine, its Chemistry and some Biological Effects".

Friday, November 23

Royal Institution (at 21 Albemarle Street, London, W.1), at 5.15 p.m.—Prof. J. D. Bernal, F.R.S.: "Lessons of the War for Scientists".

Bedson Club (in the Chemistry Lecture Theatre, King's College, Newcastle-upon-Tyne), at 5.30 p m.—Prof. G. F. Marrian, F.R.S.: "Some Aspects of the Biochemistry of the Corpus Luteum Hormone" (Sixty-first Bedson Lecture).

Institution of Electrical Engineers, Measurements Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Dr. J. M. Meek: "The Influence of Irradiation on the Measurement of Impulse Voltage with Sphere-Gaps".

Institution of Mechanical Engineers (at Storey's Gate, St. James's Park, London, S W.1), at 5.30 p.m.—Miss Verena Holmes: "The Place of Women in Post-War Engineering".

Chemical Society (joint meeting with the Local Sections of the Royal Institute of Chemistry and the Society of Chemical Industry) (at University College, Cardiff), at 6.30 p.m.—Prof. J. W. Cook, F.R.S.: "Colchicine, its Chemistry and some Biological Effects".

Association of Scientific Workers (at the Onward Hall, 207 Deansgate, Manchester), at 7 p.m.—Dr. W. A. Wooster. "Science To-day in the U S.S R.".

British Association of Chemists, St. Helens Section (at the Y.M C.A. Buildings, St. Helens), at 7.30 p.m.—Dr. N. Thorley: "Chemical Analysis by X-Rays".

Saturday, November 24

Institution of Mechanical Engineers, Graduates' Section (at Storey's Gate, St. James's Park, London, S.W.1), at 3.30 p m.—Mr. A. C. Hartley "Operation PLUTO" (Annual Lecture).

APPOINTMENTS VACANT

Applications are invited for the following appointments on o before the dates mentioned.

Clinical Psychologist to the Berkshire Child Guidance Clinic—The Medical Superintendent, Berkshire Mental Hospital, Cholsey Berks. (November 21).

Senior Engineering Assistant on the staff of the Boroug Engineer's Department—The Borough Engineer, Town Hall, We Ham, London, E.15 (November 24).

Engineering Assistant to the River Roding Catchment Board—The Clerk of the Board, National Provincial Bank Chambers, Romford Essex, endorsed 'Engineering Assistant' (November 24).

Assistant Chief Engineer by Oil Company in Trinidad—Th Ministry of Labour and National Service, Appointments Department Technical and Scientific Register, Room 670, York House, Kingsway London, W.C.2, quoting C.2881 XA (November 24).

Senior Physicist (man or woman) by British Leather Manufacturer Association, to organize and collate investigations on physical properties of leather—The Ministry of Labour and National Service, Appointments Department, Technical and Scientific Register, Room 670, Yor House, Kingsway, London, W.C 2, quoting A.1141 XA (Novembe 24).

Chief Chemist, a Junior Technical Engineer, a Combustio Engineer, and three Assistant Planning Engineers, in the Fulham Borough Council's Base Load Generating Station—The Town Clerk Town Hall, Fulham, London, S W 6 (November 26).

Chief Water Inspector—The Chief Engineer, Southend Waterworks Co., 13 Cambridge Road, Southend-on-Sea, endorsed 'Personal—Chief Water Inspector' (November 26).

Lecturer in the Mathematics and Physics Department—Th Clerk to the Governors, South-East Essex Technical College an School of Art, Longbridge Road, Dagenham, Essex (November 26)

Senior Assistant Lecturer (full-time) in Mechanical Engineering Subjects to Honours Degree and Higher National Certificat standards in the Cardiff Technical College—The Director of Education City Hall, Cardiff (November 27).

Laboratory Technician (with special experience in Histology)—The Medical Director, Ashford County Hospital, Ashford, Midd (November 28).

Assistant Lecturers (2), one in the Department of Mathematic and one in the Department of Physics—The Secretary, King's Colleg Strand, London, W.C.2 (November 30).

Demonstrator (temporary) in Physiology in the Medical School—The Registrar, King's College, Newcastle-upon-Tyne (November 30)

Deputy Water Engineer and Manager of the Warrington Corporation Waterworks—The Town Clerk, Town Hall, Warrington endorsed 'Deputy Water Engineer and Manager' (November 30).

Executive Engineers (2) in the Public Health Engineering Department, Government of Bihar—The Ministry of Labour and Nationa Service, Appointments Department, Technical and Scientific Registe Room 670, York House, Kingsway, London, W.C.2, quoting E.3013. (November 30).

Irrigation Engineers for Burma—The Ministry of Labour an National Service, Appointments Department, Technical and Scientifi Register, Room 670, York House, Kingsway, London, W C.2, quotin E 2098.A (November 30).

Physicist or Applied Mathematician, with research experience, by British Cotton Industry Research Association, to carr out theoretical and experimental studies of vibrations in machines—The Ministry of Labour and National Service, Appointments Department, Technical and Scientific Register, Room 670, York House, Kingsway, London, W.C.2, quoting A.1149.X (November 30).

Lecturer in Refractories, and a Lecturer in Chemica Technology—The Secretary, Imperial College, Prince Consort Road London, S.W.7 (December 15).

Lecturer in Physical Chemistry, and an Assistant Lecture in Chemistry—The Registrar, The University, Sheffield (December 31

Assistant Advisory Mycologist—The Dean of the Faculty o Agriculture and Horticulture, The University, Reading.

Demonstrator in the Department of Geology, and a Junio Research Worker and part-time Demonstrator in the Department of Zoology—The Secretary, Bedford College for Women Regent's Park, London, N.W 1.

Graduate Teacher of Geography at the Folkestone Count Technical School for Girls—The Divisional Educational Officer, Ol Harvey Grammar School, Foord Road, Folkestone.

Laboratory Assistant (female) of Inter. Sci. standard for work i a Biological Laboratory—The Pharmacological Department, Pharmaceutical Society, 17 Bloomsbury Square, London, W.C.1.

Lecturer in Mechanical Engineering Subjects—The Principa Erith Technical College, Belvedere, Kent.

Lecturer in Rural Science and Biology at the City of Bat Training College—The Director of Education, Education Departmen Guildhall, Bath

Library Assistant—The Secretary, Institution of Automobi Engineers, Research Department, Great West Road, Brentford, Midd

Research Assistants (should possess good honours degree Economics, Statistics or Mathematics) for the Ministry of Town an Country Planning Headquarters in London—The Ministry of Labou and National Service, Appointments Office, 1–6 Tavistock Squar London, W C 1, quoting C D 10.

Scientific Officers and Senior Scientific Officers, and Assistant Experimental Officers and Experimental Officers, to f vacancies on the scientific staffs of Government Departments—T Secretary, Civil Service Commission, Burlington Gardens, London, W.

Secretary with some knowledge of medical sciences (main wo would be preparation of abstracts of medical literature)—The He of the Department of Pharmacology, Oxford.

Senior Laboratory Steward for Department of Organic Chemistry—The Registrar, The University, Liverpool.

Teachers (part-time) for Evening Classes in Mathematics (Matric. Geography (Matric.), Elementary Physics and Chemistry f Dental Mechanics—The Secretary, North-Western Polytechn London, N.W 5.

PHYSICS Dept. Upper Circular Rd, Calcutta

ATOMIC ENERGY

FROM scientific workers, at least, there will be a warm welcome for the blend of caution and idealism which constitutes the statement on atomic energy issued in London and Washington by President Truman, Mr. Attlee and Mr. Mackenzie King on November 15 as a result of their conversations (see p. 615). Essentially, the statement embodies the conclusions reached by scientific opinion, both among those who have been directly associated with the development of atomic energy and more generally. Most of the ideas that have been put forward for the control of the atomic weapon are included in the terms of reference of the Atomic Energy Commission now to be set up under the United Nations, and in the final article of the statement there is to be sensed something of the urgency and of the overwhelming need for establishing new international machinery or organization, competent to deal with an unprecedented situation which has made some surrender of national sovereignty inescapable if mankind is to avoid disaster.

Too much must not, of course, be claimed for the statement. No decisions have yet been taken : the Commission, which is to work with the utmost dispatch, has first to agree, and agreement may be difficult. The member States of the United Nations will then have power to criticize its recommendations, and there is as yet no certainty that such recommendations will be accepted. Instruments and organizations and schemes alike have yet to be formulated and agreed. None the less, the advance is real and important. So far, the questions of the international inspection of national territories and of the removal of atomic weapons from national armouries have been discussed only by private individuals and groups. They are now to be debated by States, and the offer to abandon their present monopoly, made by the Western Powers, both challenges the temper of the world and makes possible discussion of the whole question in an atmosphere of mutual trust and not intransigence ; it also throws the onus on any who reject the resultant proposals to provide an alternative and acceptable solution.

Whatever may be the outcome of the work of the Commission, the present statement should prove a landmark in science. The affirmation that the fruits of scientific research should be made available to all nations, and that freedom of investigation and free interchange of ideas are essential to the progress of knowledge, marks the public acceptance of a truth that has always been urged in these columns, and of which the making available to the world of the basic scientific information essential to the development of atomic energy for peaceful purposes is only a particular example. The signatories met further to consider the possibility of international action "to promote the use of recent and future advances in scientific knowledge . . . for peaceful and humanitarian purposes". These general declarations must not be overlooked by scientific men, for there are still many obstacles to be overcome in the way of the free flow of scientific knowledge and interchange both of ideas and of workers. They may yet prove of service in widely different fields from that of the possible development of other methods, or of new methods, of warfare which may constitute as great a threat to civilization as the military use of atomic energy.

This contingency is expressly contemplated by the signatories of the statement, which contains no more important passage than that which affirms their intention that all further information of this character that may become available from time to time shall be similarly treated. That step, with the express declaration that the signatories of the statement are willing, as a first contribution, to proceed with the exchange of fundamental scientific information and the interchange of scientific men and scientific literature for peaceful ends with any nation that will fully reciprocate, should go far to create an atmosphere of reciprocal confidence essential to political agreement and co-operation. It is for precisely that reason that some doubts may be entertained as regards the validity of the argument that "specialized information regarding the practical application of atomic energy" should be withheld until such time as "effective, reciprocal and enforceable safeguards, acceptable to all nations" have been devised.

There are two points involved in this argument. The decision to exchange fundamental information is of necessity a general statement; but men of science must be watchful of any attempt to delimit such knowledge for the purpose of instituting a form of censorship. Knowledge is constantly extending its boundaries, and the idea that it is possible to lay down rules for the guidance of an administrative body is most dangerous.

As regards the second point, there is nothing to be gained by haphazard broadcasting of the facts regarding the industrial processes for the atomic bomb, and no objection can reasonably be raised against the intimation in the statement that the United States, Great Britain and Canada are prepared to share such detailed information, on a reciprocal basis, with other of the United Nations when such safeguards against its use for destructive purposes have been devised. That position may not, however, hold indefinitely. Speed in working out the safeguards is vital, and the urge must come from the three signatories of the statement as well as from the other nations in the civilized world to whom the offer is made, and who, as the statement rightly emphasizes, share the responsibility for devising means to ensure that the new discoveries shall be used for the benefit of mankind instead of as a means of destruction.

The United States clearly could not at present go beyond this offer; but scientific workers must see to it that the note of urgency is not lost and that the present decision regarding the industrial information is kept constantly under review. Exceptions, once admitted, are apt to create precedents, and to end by nullifying the principle at stake. Moreover, since the consensus of scientific opinion is that any secrets of the military application of atomic energy—and they may be a chimera—are unlikely to remain secret for any lengthy period of time, the long-term diplomatic drawbacks of secrecy in encouraging warranted suspicion and mistrust may outweigh su temporary advantages as may be thought to der from the present proposal.

From the diplomatic as well as from the scienti point of view, therefore, this aspect of the stateme must be kept carefully under view, and it supplies imperative reason for the Commission completi with the utmost dispatch what are suggested as t first two stages in its task: consideration of the wi exchange of scientific men and information; and t development of full knowledge concerning the natu resources of raw materials. Further, the plan designed to foster the growth of confidence fr actions, and from actions which will engender co fidence through close intercourse. While confiden may be a matter of time, the close intercourse is immediate and vital matter.

A second imperative reason for urgency is to found in the immense potentialities which atom energy offers for the material well-being of mankin Scientific men, while recognizing in the statement t substantial acceptance of their own point of vie must also accept responsibility for seeing that pub opinion recognizes what is at stake, and clear understands both the sacrifices of national sovereign which are involved in any system of internation control, and also the consequences of failure to c operate and to develop an effective scheme. If t precedent of war-time experiment is any guide, t development of atomic energy for industrial a humanitarian purposes will call for the investment very large resources in material, in man-power a in brain-power. Full and swift development will mo assuredly depend on that team-work in scien operating across national frontiers of which the W has given us such remarkable instances.

The statement rightly reminds the world that t responsibility in this matter is one that rests up the whole civilized world, and not on Great Britai the United States and Canada alone. The offer whi they have now made will provide an opportunity f the authorities of the U.S.S.R. to satisfy the desi of Russian scientific workers so conspicuously di played at the recent celebrations of the two hundr and twentieth anniversary of the Academy of Scienc in Moscow to co-operate with their fellows elsewhe If scientific men are to meet and mix freely, and learn to know one another, much will depend how far those of the U.S.S.R. in particular are enabl to co-operate.

Men of science in Great Britain at least will be one in the hope that the work of the new Commissi will give a fresh impetus to co-operation among scie tific workers generally, not merely in the control of t use of atomic energy for destructive purposes, b also in its development for peace-time use, and opening up a new atomic age. Above all, men of goo will everywhere will hope the proposals will give fre reality and purpose to the United Nations Organi tion, and foster the mutual trust and understandi among the nations upon which alone the fulle measure of co-operation is possible even in a task such world-wide scope and significance.

PROGRESS IN BIOCHEMISTRY

dvances in Enzymology and Related Subjects of Biochemistry

lited by F. F. Nord and C. H. Werkman. Vols. 4 and 5.). viii+332; and vii+268. (New York: Interscience iblishers, Inc., 1944 and 1945.) 5.50 dollars each.

THE two volumes under review maintain the high standard of their predecessors. The subjects of e articles are varied, ranging from considerations gene structure to a description of recent work on e biochemistry of Fusaria. There is not an article the two volumes which has not some interest to e biochemist who, in these days of rapid scientific vance, is becoming more and more dependent on equate and authoritative reviews.

The important subject of the structure of the cleoproteins and their connexions with genes and ruses forms the theme of articles by Gulick (vol. 4, 1) and Pirie (vol. 5, p. 1). The former article deals rgely with the subject of chemical genetics and ves a number of interesting examples of the manner which mutations occur with loss of specific chemical nctions. For example, a strain of *Neurospora* exists nich differs from the normal in its inability to syn- esize the thiazole component of aneurin (vitamin), another exists which cannot synthesize pyrid- ine (vitamin B_6) and yet another which cannot nthesize the *p*-aminobenzoic acid which it requires. pparently the last strain has lost an enzyme which concerned with the introduction of an amino group to the para position of the benzene nucleus. Other stances, concerned with the occurrence of pigments plants or of colours in insect eyes or of melanins mammalian hair, are quoted. Two examples of herited chemical anomalies in man are touched on—these are cystinuria, a congenital defect be- ving as a Mendelian recessive, and hæmophilia. he author might well have included phenyl- tonuria, a condition associated with mental defect, which phenylpyruvic acid is excreted in the urine. hese conditions of abnormal metabolism are in- cators of the parts played by the genes in estab- hing the chemical character of a living cell. Little at is definite is known of the chemical structure of nes but presumably they have the properties of cleoproteins, aggregates of which form the romosomes on or in which the genes are situated. ny gene must have the property of self-reduplication sides its power of producing in the cell the enzymic aterial or systems which characterizes the gene. It ems probable that there is much in common be- veen the gene and the virus, the physical and chem- al properties of which form the subject of the article Pirie. The latter deals in particular with tomato ishy stunt virus and strains of tobacco mosaic virus. uch is now known of these substances, which have en crystallized and analysed and which "have ecial advantages as materials for the study of the emical and physical behaviour of proteins, for they ve an unusually large number of properties that e well adapted for the quantitative study of the anges" which they undergo.

The properties of enzymes form the subjects of ticles by Pigman on the glycosidases (vol. 4, p. 41), Nelson and Dawson on tyrosinase (vol. 4, p. 99), d by Blaschko on amino-acid decarboxylases ol. 5, p. 67). Pigman gives a comprehensive survey recent contributions on the mechanism of action glycosidases with special reference to the work Helferich and his associates on the action of β-glucosidase of almond emulsin on aryl and alkyl β-glycosides. This work provides an interesting study of the influence of structure on the rate of a chemical reaction controlled by an enzyme. Pigman also introduces in his article a useful classification of the carbohydrases. The enzyme tyrosinase has now a comparatively large literature devoted to it. It has played an important part in the development of modern views of the mechanism of biological oxidations, for although Bertrand first described it in 1896, interest in the chemistry of the oxidases dates back to the classical work of Schonbein in 1856. Nelson and Dawson ably summarize present knowledge of tyrosinase as a catalyst of the aerobic oxidations of both monohydric and *o*-dihydric phenols and discuss the question as to whether the enzyme is a single protein having two distinct activities or whether it is a mixture of two distinct proteins having different chemical activities. They finally conclude that it is a single copper protein entity having two enzymic activities. Blaschko deals, in his article, with amino-acid decarboxylases of mammalian origin, pointing out their importance in the body in the elaboration of histamine, adrenaline and taurine. It will be of interest to discover whether mammalian amino-acid decarboxylation depends on the presence of phospho-pyridoxal, as is now known to be the case with bacterial amino-acid decarboxylases.

The reversible intermolecular transfer of an amino group from an α-amino-acid to an α-keto-acid, now known as transamination, forms the theme of an article by Herbst (vol. 4, p. 75). This author deals first with transamination in model systems and then with enzyme catalysed systems, paying attention to the pioneer work of Braunstein and Kritsman and to the later work of Cohen on the kinetics of transaminase activity in tissue extracts. It is of interest that those substances which are most actively transaminated (*l*-glutamic acid, oxalacetic acid, pyruvic acid) hold key positions in carbohydrate and amino-acid metabolism, the kinetics of which, therefore, may in certain circumstances be controlled by the presence of transaminases.

One of the most striking advances in recent years has been the discovery and exploration of the natural antibiotics, of which penicillin is the most spectacular example. Hotchkiss (vol. 4, p. 153) contributes an article on gramicidin, tyrocidine and tyrothricin which is of the greatest interest in presenting information on the properties and possible modes of action of these substances. Dubos in 1939 described the preparation from cultures of an ærobic spore-forming organism (*B. brevis*) of a protein-free product having highly antibacterial properties. This product, termed tyrothricin, was separated by crystallization into two alcohol-soluble polypeptides, gramicidin and tyrocidine. Gramicidin and tyrothricin in very small quantities prevent the development of a variety of Gram-positive micro-organisms *in vitro* and under some conditions *in vivo*. Tyrocidine also kills Gram-positive and Gram-negative bacteria *in vitro* but not in the presence of serum proteins. Tyrothricin has been found to modify the course of infections in man and animals, but it is too toxic to the host to have more than a limited application. Gramicidin and tyrocidine have molecular weights about 3,000 and seem to contain a large proportion of *d*- or unnatural amino-acids. Hotchkiss presents evidence in support of the view that gramicidin may exert its bacteriostatic effects by blocking a metabolic process involving the uptake of phosphate and thus interfering with the cell's normal synthetic operations. It has pronounced effects on the metabolism of susceptible bacteria when these are examined in the form of washed suspensions. Tyrocidine is bactericidal in action, bringing about a release of soluble cell constituents from the susceptible bacteria. The evidence indicates that, apparently, tyrocidine "so modifies the cell surface that vital soluble metabolites such as nitrogen compounds, inorganic phosphate and phosphate esters are washed out of the cell". The results illustrate the variety of ways in which antibiotics may affect susceptible cells, by interference with processes essential to normal metabolism or by modification of physical conditions whereby the cell equilibria are upset.

Jensen and Tenenbaum give a brief account (vol. 4, p. 257) of recent work on the influence of hormones on the enzymic activities of various tissue preparations. The hormones dealt with include those of the pituitary group, insulin, thyroid, epinephrine and those of the adrenal cortex. There is no information as yet on the possible role of these hormones in specific enzyme processes and no evidence has been obtained that they themselves are enzymes or essential components of enzyme systems. They affect the courses of enzyme regulated reactions apparently only in the intact cell or in the body.

The influence of nicotinamide on enzyme reactions forms the subject of a comprehensive article by Schlenk (vol. 5, p. 207). Nicotinamide sprang into prominence in 1934 when it was discovered by Warburg and Christian, and by Euler, Albers and Schlenk, that it was a constituent of coenzymes essential for the activity of certain dehydrogenase systems. Two years later, Kohn and Elvehjem prepared a liver concentrate which cured chick dermatitis and dog black tongue. Elvehjem and his colleagues then isolated nicotinamide from the concentrate and showed that nicotinic acid administration would cure black tongue. Thus the discovery of the vitamin activity of nicotinic acid followed the finding that it is an essential constituent, in the cell, of respiratory processes. It is now generally held that the biological importance of nicotinic acid lies in its necessity for the building up in the body of coenzymes of dehydrogenases. Schlenk describes the results of work carried out on the structure and properties of the nicotinamide nucleotides, and on their mode of action as coenzymes. He describes methods for their quantitative determination and he also summarizes recent work on the interference of carcinogenic products with dehydrogenase activities. He deals with investigations on the fate of nicotinic acid in the body, on the enzymic breakdown of the nicotinamide dinucleotides, and on the specific inhibitive action of nicotinamide on this breakdown.

The central role of pyruvic acid in cell metabolism is the theme of an article by Stotz (vol. 5, p. 129), who considers recent advances in pyruvate metabolism. Stotz deals with the wealth of data accumulated on this subject (he cites 221 references) and discusses the part played by pyruvate in glucolysis, and by the various dehydrogenases and phosphorylating systems involved. He describes work on pyruvate dismutation, decarboxylation, oxidation and condensation, processes all requiring the presence of diphosphoaneurine (vitamin B_1) and on the parts played by pyruvate in acetylcholine synthesis in brain, in carbon dioxide fixation in bacteria and animal tissues, in transaminations, and in fatty acid metabolism. Pyruvate occupies a key position most of the important phases of cell metabolis bearing out a thesis put forward by the review more than twenty years ago[1] that pyruvate may w be considered a primary metabolite, a substan which occupies an essential role in the synthet operations of the cell.

Potter contributes a most interesting and thoug ful article (vol. 4, p. 201) on biological energy tran formations, discussing details of glycolytic, oxidati and phosphorylative mechanisms. He includes ve useful data on the methods of analysis used in t study of these mechanisms, and gives tables of ass results in tissues, with particular reference to co ponents of the succinoxidase system, to adenosinet phosphatase, to coenzymes of dehydrogenases and riboflavin. He discusses the subject in relation the metabolism of tumours.

While there is an inevitable overlap between t articles, dealing with cell metabolism, of a number the contributors to the volumes under review, th constitutes, in the reviewer's opinion, no demer Knowledge of the details of cell metabolism is e panding so rapidly that only good can come from t presentation of different points of view, even thou much common ground is covered by the exponen of these views.

Leibowitz and Hestrin (vol. 5, p. 87) discuss t question of the fermentation of the oligosaccharid (for example, maltose, sucrose and lactose) as distin from that of the breakdown of polysaccharides (su as starch and glycogen). They deal in a detailed w with the indirect fermentation theory of Fischer a the direct fermentation theory of Willstätter, a assemble the evidence bearing on the mechanism the fermentation of the oligosaccharides with speci reference to the parts played by phosphorylati mechanisms. They deal also with the interesti syntheses of polysaccharides (levan and dextran) fro sucrose by soluble cell-free enzyme obtained fro bacteria.

Limitation of space alone prevents more th mention of the instructive article by Nord and M on recent progress in the biochemistry of Fusa (vol. 5, p. 165), of the account of the chemistry of t coagulation of blood (vol. 5, p. 31) by Chargaff w has contributed so much to this subject, of t description of a number of enzymic processes co cerned with the metabolism of sulphur compoun (particularly cysteine and methionine) by Smyt (vol. 5, p. 237), and finally of the useful article Brode (vol. 4, p. 269) on the absorption spectra vitamins, hormones and other biologically importa substances.

J. H. QUASTEL.

PATRICK GEDDES

Patrick Geddes

Maker of the Future. By Philip Boardman. Pp. xix 504+13 plates. (Chapel Hill, N.C.: University North Carolina Press; London: Chapman and Ha Ltd., 1944.) 30*s*. net.

IN so much as Mr. Boardman succeeds in conveyi a vivid picture of Geddes' dynamic personalit the wide sweep of his interests, and to some exte of the contribution which Geddes made as a teach as a pioneer in sociology and as a creative thinker town and regional planning, he may be held to ha cceeded in his purpose. Patrick Geddes is probably ost widely known as the joint author with J. Arthur omson of "The Evolution of Sex" and "Outlines General Biology", and Mr. Boardman's study ould indicate to a fresh generation something of e vitality, the stern common sense and realism, the eadth of scholarship which marked Geddes in his nderings as student or as professor, and brought m into more creative enterprises than any other n in the three decades preceding the outbreak of e War of 1914–18. His adventurous spirit stands t afresh from these pages, and the appeal of the ok to youth is enhanced by the picture of his oneer enterprise in starting a students' hall of sidence at the University of Edinburgh or of his bsequent contribution to the renovation of Edin- rgh Old Town. Prof. Geddes' services in adult ucation, as an apostle of town-planning and the doubted parent of the regional survey, his un- asing warfare on specialization, all find a place, ough one would not draw from this book quite the pression of Geddes as inspiring a new and creative nception of social service to which Mumford paid bute in "The Condition of Man".

But it is essentially a portrait rather than an terpretation that Mr. Boardman gives us, and the cord of the stages and the manner in which the ung scholar of Perth Academy and the student der Huxley at the Royal School of Mines battled s way to the chair of botany at University College, undee, might well be clearer in places. Somewhat nfused, too, is the record of the myriad activities, ch as the civic surveys of Dunfermline and Dublin, s direction of "The Masque of Learning" in London d Edinburgh, his influence on the Town Planning nference Exhibition in London in 1910, the Indore port on Town Planning and on university reform, hich he pursued for thirty-one years from that chorage. The relevance of those activities and eas, especially in education and in the field of uversity reform, to current discussions is obvious, d there is much in the book that is stimulating d suggestive—not the least in the finely sketched cture of Geddes' relations with his son Alasdair d the demonstration of the practical value of his ucational theories.

When all that is said, the book, admirably pro- ced and printed though it is, is somewhat dis- pointing. Within the compass of five hundred ges, one expects something more substantial, and e perceptive preface contributed by Mr. Lewis umford, himself a distinguished American disciple Geddes, cannot redeem the deficiencies of scholar- ip or critical appraisal of the significance of Geddes' e and thought and his influence on education or on gional planning. It is not sufficient for Mr. Board- an to disclaim any pretensions to a definitive ography: his skill and industry in reducing to the esent limits the scattered, imperfect and almost manageable records of a remarkable career call ly for admiration; but having done so much, Mr. ardman should not have been content merely to cord this constant interpenetration of the general d the particular, the philosophical and the scientific tlook, the universal and regional which character- ed Geddes, and late in life tended to engender redom.

The real defect of what purports to be a serious udy is not, however, this lack of scholarship—and it noted we have here yet another expensively oduced book shorn of the few pages necessary to supply complete bibliographical information—it is a defect of technique. Fiction has its place in the imaginative interpretation of history, as Margaret Irwin, for example, has shown; and there will always be readers to whom the picture of Montrose will be conveyed more effectively through the medium of such a book as "The Proud Servant" than in such a brilliant study as John Buchan's "Montrose". Both methods have their place, but that place is not in the same book, and Mr. Boardman's fatal mistake in this volume has been the combination of fictional and straightforward biographical technique. Whatever picturesqueness his lapses into fiction may introduce, they confuse the narrative. It is unfortunate that Mr. Boardman should have been tempted into the use of a device which mars a serious study.

R. BRIGHTMAN.

TIMBER RESOURCES OF BRITAIN

The Wood from the Trees

By Richard Jefferies. (London: The Pilot Press, Ltd., 1945.) Pp. 143+16 plates. 9s. 6d. net.

THE contents of this book can be briefly stated. There are three clearly defined sections, the first of which deals with the main forest resources of the world, the methods of preparing timber, and the pre-war and possible post-war flow of timber from exporting countries to Great Britain. In the second section Jefferies describes the role and uses of timber as an implement of war and speculates about the probable fate of timber resources in invaded and other countries. Despite the author's real interest in the uses, distribution and potential value of wood, however, it is clearly apparent that the theme and the *raison d'être* of this book lie in the third section.

Here the *motif* is the imperative necessity for the greater development of timber resources in Great Britain. This is repeatedly brought out and might have gained greater emphasis if it had been stated once or twice less often. One reason for the previous neglect of our trees, declares the author, is that private owners have hitherto not realized the true value of wood. Since the State also has not been particularly diligent in its afforestation programmes, we have been faced by two wars in an unprepared condition and have had to divert considerable shipping space to bring in a bulky commodity, much of which could have been grown at home. Therefore, continues Jefferies, who is no doctrinaire politician, neglected forests of Great Britain must be taken over by the State and become part of a planned forestry programme. Besides already existing woodlands, schemes of afforestation should be drawn up for the several million acres of rough grazings which are not specially favourable for agricultural development. All this, and much more, is persuasively argued, and, even if it fails to influence Government policy, should at least stimulate some owners of private forests to put their wood in order.

"The Wood from the Trees" would have carried greater weight, however, if, in addition to his plea for home-produced timber, Jefferies had been more revealing about the kind of trees he advocated and the relative amounts and geographical distribution of hardwood and softwood he would grow and his reasons for so doing. The book is attractively finished with clear and relevant photographs and some helpful 'isotype' diagrams; no reason is given for the absence of an index.

T. H. HAWKINS.

Science and the Planned State

By John R. Baker. Pp. xvi+102. (London: George Allen and Unwin, Ltd., 1945.) 7s. 6d. net.

THIS volume purports to give a careful analysis and criticism of the totalitarian view of science. Considering first the proposition that science exists only to serve the material wants of man, upon which he suggests that the whole of the totalitarian view of science is based, Dr. J. R. Baker proceeds to discuss the 'freedoms' which best serve the cause of discovery. He then deals briefly with science under totalitarianism, but more particularly with science in the U.S.S.R., the deficiencies of Soviet science and the genetics controversy, and in his last chapter on the duties of scientific men to society endeavours to indicate some of the ways in which they may use their special talents for the benefit of others. As in his book, "The Scientific Life", Dr. Baker insists on the importance of the element of chance in scientific discovery and the encouragement of the amateur. In dealing with such a topical subject, it would be strange if Dr. Baker had not something pertinent and suggestive to say, and this fresh plea for the preservation of freedom of inquiry, for valid argument and insistence on the cultural value of science is to be welcomed.

None the less, this is scarcely a book which will add to Dr. Baker's reputation. It cannot be claimed that he brings to his task the objectivity that should characterize the scientific man. He consistently fails to distinguish between the planning of discovery, which is manifestly absurd, and planning the general manner in which available scientific resources should be used. Dr. Baker is inclined not to see the facts that are uncomfortable or disconcerting for his theory, and the real contribution of his book to the debate on the planning of science is slight, however unexceptionally it maintains that science does not exist solely to serve man's material needs, that a thorough-going scheme for the central planning of research would gravely damage science or that totalitarianism is the form of government least in accord with scientific principles. Nor does Dr. Baker strengthen his argument when, for example, he quotes A. Szent-Györgyi second-hand from the *World Digest*, or the Archbishop of Canterbury from the *Sunday Express*. Finally, the numbering of the references in alphabetical sequence at the end of the volume, even though it has the authority of Royal Society practice in biological papers, instead of in numerical sequence as they occur, cannot be allowed to pass without protest from at least one reader.

Metallography of Magnesium and its Alloys

A translation from the German by the Technical Staffs of F. A. Hughes and Co., Ltd., and Magnesium Elektron, Ltd., of "Metallographie des Magnesiums und seiner technischen Legierungen", by Walter Bulian and Eberhard Fahrenhorst. Pp. xi+117. (London: F. A. Hughes and Co., Ltd., 1944.) 15s.

MESSRS. F. A. Hughes and Co. and Magnesium Elektron, Ltd., have already placed the metallurgical world deeply in their debt by their excellent translation of Beck's "Technology of Magnesium and its Alloys". They have now increased that debt by translating another German book dealing with a much narrower part of the magnesium field: Bulian and Fahrenhorst's "Metallographie des Magnesium und seiner technischen Legierungen". In one respect this translation differs from that of the earlier bo a very valuable feature of which was that footnot correcting errors of statement, important omissi or biased points of view, were freely added to the te Perhaps it is a pity that this has not been done the translation under review; but it must be mitted that such notes are not nearly so needed i book like the present one, which is written aroun series of photographs, whereas in Beck's book personal opinion and bias of the writer had mu more play.

The book commences with a chapter on polishi and etching technique and then reproduces 2 photomicrographs and 10 macrographs, which their high level of excellence confirm the value of t technique described. They are well selected illustrate the different types of structures which described in the text. A useful bibliography bri to a close this book, which can be confidently reco mended to all who have to deal with the microscop examination of magnesium alloys.

Through My Garden Gate

By Newman Flower. Pp. v+94. (London, Toront Sydney and Melbourne: Cassell and Co., Ltd., 194 5s. net.

THIS is a delightful book, well worthy of noti in a scientific journal, because the man of scien like all other sensible men, may know the sim pleasure of working in and enjoying his garden. T book is a collection of garden observations, "though and philosophy by a keen amateur gardener of ma years standing". He describes "the garden of thousand joys", which, he says, is the only na for the garden which is loved by the person w works in it. He does not write for the wealthy pers who owns a garden in which the work is done by ag menials, nor for a gardening mechanic who mere makes a garden. He writes for those for whom garden means what it means for him—a belov place where one toils and plants one's thoughts. H book is one which can be picked up at any tin for through its pages runs a warm and a high intelligent love for the things of the garden.

The Statesman's Year Book

Statistical and Historical Annual of the States of t World for the Year 1945. Edited by Dr. M. Epste Eighty-second annual publication, revised af Official Returns. Pp. xxxvi+1479. (Londo Macmillan and Co., Ltd., 1945.) 30s. net.

THIS indispensable annual again makes regular appearance with revision up to the e of the first quarter of the year. The end of the W in Europe came too late for inclusion in the histori summaries and so, for the last time, Germa appears in her pre-war state and with her N leaders. Revision in war-time is far from easy, many States have published no statistical retur of production and trade. Wherever possible, ho ever, recent figures in many parts of the Emp and in the United States have been included. T invaluable bibliographies attached to each secti have been thoroughly revised and in some ca extended. This is specially noteworthy in regard the United States. Two coloured maps show spectively the Russo-Finnish boundary of armistice of 1944 and world airways for internatio transport. The volume retains its usual size a compact form.

THREE-POWER DECLARATION ON ATOMIC ENERGY

THE statement on the future use of atomic energy, prepared after consultations held in 'ashington between the President of the United ates and the Prime Ministers of Canada and the nited Kingdom, was read at the White House and the House of Lords and the House of Commons on November 15. The text is as follows :

The President of the United States, the Prime inister of the United Kingdom, and the Prime inister of Canada have issued the following statement :

1. We recognize that the application of recent ientific discoveries to the methods and practice of ar has placed at the disposal of mankind means of estruction hitherto unknown, against which there an be no adequate military defence, and in the employment of which no single nation can in fact have monopoly.

2. We desire to emphasize that the responsibility or devising means to ensure that the new discoveries hall be used for the benefit of mankind, instead of a means of destruction, rests not on our nations lone, but upon the whole civilized world. Nevertheless, the progress that we have made in the development and use of atomic energy demands that we ake an initiative in the matter, and we have accordingly met together to consider the possibility of iternational action :

(*a*) To prevent the use of atomic energy for destructive purposes.

(*b*) To promote the use of recent and future advances in scientific knowledge, particularly in the tilization of atomic energy, for peaceful and humanarian ends.

3. We are aware that the only complete protection for the civilized world from the destructive se of scientific knowledge lies in the prevention of ar. No system of safeguards that can be devised ill of itself provide an effective guarantee against roduction of atomic weapons by a nation bent on aggression, particularly since the military exploitation of atomic energy depends, in large part, upon the same weapons and processes as would be required for industrial uses. Nor can we ignore the ossibility of the development of other methods or f new methods of warfare, which may constitute as great a threat to civilization as the military use of atomic energy.

4. Representing, as we do, the three countries which possess the knowledge essential to the use of tomic energy, we declare at the outset our willingness, as a first contribution, to proceed with the xchange of fundamental scientific information ; and the interchange of scientists and scientific literature or peaceful ends with any nation that will fully eciprocate.

5. We believe that the fruits of scientific research hould be made available to all nations, and that reedom of investigation and free interchange of deas are essential to the progress of knowledge. In pursuance of this policy, the basic scientific information ssential to the development of atomic energy for peaceful purposes has already been made available to the world. It is our intention that all further information f this character that may become available from me to time shall be similarly treated. We trust hat other nations will adopt the same policy, thereby creating an atmosphere of reciprocal confidence in which political agreement and co-operation will flourish.

6. We have considered the question of the disclosure of detailed information concerning the practical industrial application of atomic energy. The military exploitation of atomic energy depends, in large part, upon the same methods and processes as would be required for industrial uses. We are not convinced that the spreading of the specialized information regarding the practical application of atomic energy, before it is possible to devise effective, reciprocal, and enforceable safeguards acceptable to all nations, would contribute to a constructive solution of the problem of the atomic bomb. On the contrary we think it might have the opposite effect. We are, however, prepared to share, on a reciprocal basis with other of the United Nations, detailed information concerning the practical industrial application of atomic energy just as soon as effective enforceable safeguards against its use for destructive purposes can be devised.

7. In order to attain the most effective means of entirely eliminating the use of atomic energy for destructive purposes and promoting its widest use for industrial and humanitarian purposes, we are of the opinion that at the earliest practicable date a commission should be set up under the United Nations to prepare recommendations for submission to the organization. The commission should be instructed to proceed with the utmost dispatch and should be authorized to submit recommendations from time to time dealing with separate phases of its work.

In particular, the commission should make specific proposals :

(*a*) For extending between all nations the exchange of basic scientific information for peaceful ends.

(*b*) For control of atomic energy to the extent necessary to ensure its use only for peaceful purposes.

(*c*) For the elimination from national armaments of atomic weapons and of all other major weapons adaptable to mass destruction.

(*d*) For effective safeguards by way of inspection and other means to protect complying States against the hazards of violations and evasions.

8. The work of the commission should proceed by separate stages, the successful completion of each of which will develop the necessary confidence of the world before the next stage is undertaken. Specifically, it is considered that the commission might well devote its attention first to the wide exchange of scientists and scientific information, and as a second stage to the development of full knowledge concerning natural resources of raw materials.

9. Faced with the terrible realities of the application of science to destruction, every nation will realize more urgently than before the overwhelming need to maintain the rule of law among nations and to banish the scourge of war from the earth. This can only be brought about by giving wholehearted support to the United Nations Organisation, and by consolidating and extending its authority, thus creating conditions of mutual trust in which all peoples will be free to devote themselves to the arts of peace. It is our firm resolve to work without reservation to achieve these ends.

BRITISH ANTI-LEWISITE (*BAL*)

By Prof. R. A. PETERS, F.R.S., Dr. L. A. STOCKEN AND Dr. R. H. S. THOMPSON

Department of Biochemistry, University Museum, Oxford

IN the first fortnight of the War (1939) fundamental research was initiated in the Oxford Department of Biochemistry by Peters and carried out under his direction by a group of workers as an extra-mural research with the support of and for the Chemical Defence Research Department, Ministry of Supply; the object was to find antidotes for vesicants, both arsenical such as lewisite ($CH.Cl : CH.As.Cl_2$) and also those of the mustard gas type. In this brief review, the main facts are given about the discovery of the antidote to lewisite known as *BAL*, owing to its medical importance; more detailed papers based upon the original reports are being prepared. An attempt is made to include the more relevant work from elsewhere and also to focus the main stages in this discovery, as this may prove useful in planning future work of this type.

Research upon the biochemical lesion in aneurin (thiamin) deficiency especially in Oxford had established that serious pathological change in the brain was induced by a partial failure of an enzyme system, the 'pyruvate oxidase', due to deficiency of an essential component, aneurin pyrophosphate (cocarboxylase)[1]. In 1936, Peters[2] reported that the vesicant substance dichlordiethylsulphone had a selective action upon the enzyme system oxidizing lactate in brain, poisoning the pyruvate component, like the enzyme inhibitor iodoacetic acid; since the latter is a weak vesicant, he suggested that the similar vesicant effect of the two substances might be related to this action. He also found that sodium arsenite in very small concentrations gave a like effect[3]; it had been known previously that oxidations were poisoned by arsenite[4] and especially α keto acid oxidations[5]. These observations focused attention upon the possibility that partial failure of an enzyme could be directly responsible for the pathological change and suggested which enzyme this might be.

Another line of thought came from much earlier work in 1923–26 carried out in this laboratory by E. Walker under the direction of Peters with the object of throwing light upon the fundamental problem of chemical constitution and toxicity of chemical warfare agents in extension of earlier work at Porton[6] and of gaining thereby therapeutic advances. Arising out of the stimulus due to Hopkins' discovery of glutathione, arsenicals such as diphenylchlorarsine were found to abolish the fixed —SH in washed muscle tissue[7] and also in the active layer of skin; hence there was interference in glutathione catalysis[8]. As the —SH reaction could not be restored by cyanide treatment[9], chemical combination (rather than oxidation) was suggested. Though for security reasons this work was only published in part in 1928[10], it was in progress independently and about the same time as that of Voegtlin and his colleagues (1923–25)[11], who advanced the view that the toxic action of arsenic on living cells was due to its reaction with certain essential thiol compounds present in protoplasm. Together with their work upon the therapeutic arsenicals, ample reason was given for directing attention to —SH groups as possible receptors arsenic, an emphasis which was strengthened work in subsequent years, for example, especia Rosenthal[12]. These ideas were also reinforced by proofs[13] that iodoacetate readily combined with — compounds and suggested the hypothesis that arse poisoned an —SH component of the enzyme. A furt most important point was supplied by Cohen, Ki and Strangeways[14], when they showed that th arsinites of type $R\,\mathrm{As}(SR^1)_2$ were dissociable alkaline solution, because this gave grounds for belief that reversal of the toxicity might pro possible.

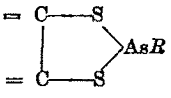
Hence the idea that the activity of arsenicals due to a selective action upon the pyruvate enzy- system and that some essential —SH component attacked formed the starting point of the resear for an antidote to lewisite. Owing to the rapidi with which substituted chlorarsines are hydrolys it was natural to consider that the effects of arseni vesicants on the skin are special examples of general action of arsenoxides upon living cells; vesicant action would be conditioned by the lipo solubility of the chlorarsines which allows them penetrate the keratin layer and so reach the cells the epidermis, dermis and capillaries.

Early in the War, fresh work by Peters, Sincl and Thompson[15] supported the idea of a selecti action of sodium arsenite and of lewisite on enzym and of their powerful action on the pyruvate syste since 50 per cent inhibition of the activity was pr duced by concentrations of 15 × 10^{-6} *M* (abo 100 µgm/gm. brain brei). Some other enzymes su as succinodehydrogenase were much less strong affected, if at all. *In vivo*, also, it was proved th poisoning with arsenite led to an elevation of blood pyruvate level, confirming that the oxidati of carbohydrate was powerfully poisoned at pyruvate stage. This was entirely analogous to raised blood pyruvate levels in thiamine deficiency but with the difference that the missing active co stituent was the protein: the coenzymes withsto the poison[17]. All this proved that the pyruva oxidase system could be confidently used as an *vitro* test for the exploration of the problem, a throughout the work it fully justified this beli Evidence[18] was soon forthcoming that an —SH gro was essential for its activity, confirming a previo guess.

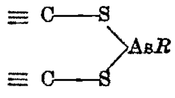
In spite of these indications, in enzyme and anim tests carried out by Sinclair[19] early in 1940 no mon thiol compound, or dithio compound (such as dieth dithiocarbamate) was effective, even protectivel against lewisite or arsenite. This applied indeed glutathione, which in large excess had been sho by Voegtlin and colleagues and Eagle[20] to sh activity against therapeutic arsenoxides. Again mo puzzling of all, as in Strangeway's experiments[21], t compounds of arsenicals with thiols could be as tox as the original arsenical; this point was stressed wi fresh evidence by Ing and Robinson[22] and can nev be safely overlooked in dealing with the behavio of new thioarsinites *in vivo*. At this stage the possib lines of progress seemed narrow; they were, perha more systematic trial of other thiols without furth biochemical guidance; and a study of the relati dissociation of various thioarsinites, often urged Philpot; neither of these lines was followed the because Stocken and Thompson started to g further information upon the interaction of th groups in proteins by analysis of compounds onic with an —SH protein product, partly for the damental study and partly to provide useful pre- inary information for examining the immuno- ical behaviour of arsenical proteins. The experi- nts were analogous to Rosenthal's, but differed in protein used and in their analysis of its arsenic l —SH content. This stage proved crucial and led a logical solution of the problem.

After treating aqueous solutions of kerateine, the uced product of keratin, containing many —SH ups[23] (the only protein of high thiol content then essible) with lewisite under physiological condi- ns of temperature and pH, Stocken and Thompson und that the arsenic content of the lewisite-kera- ne compound could be correlated rather closely th the thiol content of the parent protein, being lependent of the concentration of lewisite above a iting value[24]. This compound was stable on lysis. Oxidation of the —SH groups to the S—S— form (metakeratin) before treatment with isite led to large reduction in the amounts of enic combined. It was highly significant that in ite of large excess of lewisite, 75 per cent of the enic found in the lewisite compound was in com- ation with two thiol groups. This fact together th the ease of re-oxidation of the kerateine to the ulphide form led them to the hypothesis that the h toxicity of lewisite and of trivalent arsenicals in neral was due to their ability to combine with the ential —SH groups in certain tissue proteins, tably the enzyme concerned, to form stable enical rings. On chemical grounds compounds of pe I would be expected to be more stable than mpounds of an arsenical with two molecules of a onothiol of Type II.

I



II

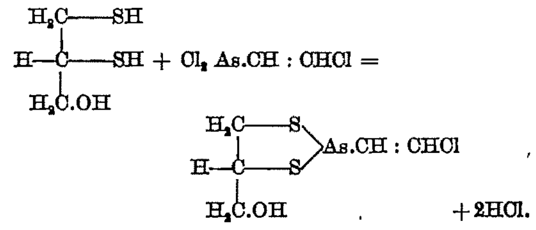


Hence simple dithiol compounds might form atively stable ring compounds with lewisite or her trivalent arsenicals and so compete successfully th 'dithiol' proteins in the tissues. In this case ioarsinites formed with monothiols would dissociate as to let their arsenic combine in ring formation th tissue thiol; this in its turn might be slightly ore dissociable than the ring formed with simple thiols. (Experimental evidence for this was pro- iced later by comparing relative rates of hydrolysis different types of thioarsinites and of lewisite- rateine[25].)

Antidote Activity of Simple Dithiols

The study of therapeutic possibilities began in 1940 th an investigation of simple small molecular 1 : 2 d 1 : 3 dithiols (Stocken and Thompson). (It may mentioned that in a related research it had been und by Philpot that small molecular fatty acids netrated the skin much more readily than long- ain compounds.) First to be tested was toluene hiol (the B.D.H. spot reagent) with promising sults on the enzyme, followed by ethane dithiol. ither of these compounds proved really suitable the objective of skin treatment and the new com- und 2 : 3 dimercaptopropanol (III) was made; as is was a penetrant oil it proved very satisfactory. the pure state it is about 6 per cent soluble in ter. The reaction with lewisite is :

III



This 'dithiol', to which the name *BAL* (British anti-lewisite) was given by the Americans, proved highly effective in stopping the toxic action of lewisite upon the pyruvate oxidase system in brain. Unlike all other thiol compounds tried, concentrations of 10^{-1}mM *BAL* gave almost complete protection against the 50 per cent inhibition of enzymatic activity produced by 15 μM lewisite oxide under these conditions.

A further most important point was now established: *BAL* could reverse the toxic action as well as prevent it, provided that the toxicity had not been too long established. It could also neutralize the lewisite inhibition of skin respiration. None of these effects was produced by monothioethylene glycol or by cysteine in equivalent concentrations. Later experiments confirmed the hypothesis that the cyclic thioarsinites were less toxic than lewisite and non-cyclic thioarsinites by showing that the toxicity of lewisite was much more reduced by combination with *BAL* than with monothioethylene glycol[25].

Treatment of Arsenical Burns with Dithiol Compounds

In agreement with the *in vitro* biochemical tests, rats and guinea pigs contaminated with lewisite could be saved by inunction with *BAL* (and also by injection of aqueous solutions of *BAL*) up to periods of two hours after contamination at a time when the animals are seriously ill. Finally, tests upon human volunteers contaminated with lewisite carried out both at Oxford[26] and Porton[27] showed that vesication by lewisite and by phenyldichlorarsine can be prevented by the application of *BAL* as late as one hour after contamination, that is, at a time when well-marked signs of injury to the skin (erythema and œdema) had developed. In many cases the residual erythema twenty-four hours after treatment was considerably less both in size and intensity than that already present at the time of treatment; in some of the experiments the subsidence of the skin oedema following treatment was sufficiently rapid to suggest an actual reversal of the underlying pathological change brought about by the lewisite. In contrast to these results with *BAL*, both in rats and in human tests, monothioethylene glycol did not influence the severity of vesication. These results have been confirmed many times, and extended in the United States and in Canada. It has been shown in Oxford by Mann and Pirie, at Porton[28] and also in the United States[29] that *BAL* suitably administered will prevent the destruction of a rabbit's eye up to periods of twenty minutes after contamination. Much effort and time has been expended both in Great Britain[30] and in the United States[31] in the preparation of satisfactory ointments, the details of which lie outside the scope of this review; this work forms a valuable basis for inunction treatment.

Practically all the above facts are contained in reports presented to the Ministry of Supply in 1940, 1941 and 1942[32]. Several other facts about *BAL* were also discovered at this time. *BAL* treatment of lewisite burns in rats was followed by a marked increase in the elimination of arsenic in the urine during the succeeding twenty-four hours, even when treatment with *BAL* is delayed for one hour after contamination, and when systemic toxic signs are already present. (Results confirming and extending this were reported by Graham and Chance, Edinburgh (1944)[46a] and by Zbarsky, Monson and Young in Canada in 1944.) Fæcal excretion of arsenic was not significantly affected. The severe diarrhœa invariably present in the untreated rats was completely prevented. Analysis of the excised skin showed a reduction in the amount of arsenic present in the contaminated area (confirmed by Chance[46b]). An unidentified thiol was rapidly excreted in the urine of rats and rabbits after subcutaneous injection of *BAL*.

Small amounts of *BAL* placed upon the skin produced in human subjects an erythema persisting for two hours, and in the case where 1 c.c. of *BAL* was rubbed into the human forearm, there was also lacrymation. These effects were transient, but repeated application of *BAL* can produce sensitivity[33]. By subcutaneous injection in rats, *BAL* had a toxicity of about 110 mgm./kilo (LD 50); this work was extended by Gaddum and Boyland; a reference standard *BAL* has been prepared in Oxford[34].

Fell and Allsopp (1941)[35] found that tissue cultures severely poisoned with lewisite largely recover when treated with *BAL*, thereby showing direct antidote effects upon cells (their findings have been confirmed and extended by Harrison and Randoll[36]). Further studies upon enzymes at Cambridge and in the United States[37], and at Oxford[38] by Stocken, Thompson and Whittaker, have shown that enzymes in tissues and isolated enzymes are protected by *BAL* from the toxic effects of lewisite and arsenicals; in the work by Van Heyningen hexokinase poisoning by lewisite was reversed by glutathione as well as by *BAL*, whereas pyrophosphatase and succinic dehydrogenase responded only to the dithiol. Enzyme studies on the nature of *BAL* inhibition have also been made by Webb and Van Heyningen under Dr. M. Dixon and in the United States; the former consider that *BAL* inhibits specifically enzymes containing metals, owing to its high affinity for them.

Pharmacological and pathological work upon *BAL* has been reported by Calder and Fosse (Porton) and in detail from the United States (1943). Much work of varied character has been in progress in Edgewood Arsenal, United States, upon *BAL* and other dithiols. For the last two years Spray[39] has worked upon metabolism of *BAL*. As an interesting application, Lovatt Evans found some prophylactic and therapeutic action of *BAL* in arsine poisoning in various species of animals and against the hæmolysis; independently, Levvy, of the Edinburgh team, showed that ethane dithiol protected mice against the lethal effect of arsine[40].

We may note at this stage that in addition to the practical applications, the discovery of *BAL* forms an important advance in theory. The theory that a biochemical lesion in a tissue formed by the partial blocking (as by the partial deficiency) of an enzyme system can cause pathological damage is strongly supported; the poison produces in effect an enzyme deficiency. The idea that the site of attack of trivalent arsenicals is upon essential —SH groups in this enzyme-protein is confirmed. That interference with the degradation of carbohydrate at the pyruvate stage is serious for tissue cells is supported by the damage produced by low concentrations of t arsenical to the pyruvate system, and by the accum lation of pyruvate in the blood produced in arsenic poisoning. It is surely also very significant th pathological change can be proved to be reversib

Chemistry of the Dithiols

Several 1 : 2 and 1 : 3 dithiols, prepared by t action of hydrosulphide on the corresponding halogen compounds, were condensed with dichl arsines, aldehydes and ketones giving rise to dit arsenoles, dithiarsenanes, dithiolanes and dithianes

Gasson, Millidge and Woodward[50] were responsi for the adaptation to technical manufacture and t introduction of stabilizers for the distillation proce In an attempt to avoid the use of bromine, Ing a Robinson[41] succeeded in raising the yield of dichl propanol from 40 per cent[42] to 64 per cent by the u of ether – HCl as a solvent for the chlorination. Sin however, the conversion to *BAL* requires a high temperature and pressure it was not convenient take advantage of this discovery on the large sca Work was initiated in Oxford early in 1941[32] in t attempt to get less toxic dithiols and some wi higher water solubility which would be more favou able for injection. This problem has also been pursu intensively in the United States. So far, with t exception of the discovery of *BAL Intrav* by anoth British group, which is separately reported, this wo has not brought to light such a compound. It interesting to note that 1 : 3 dimercapto 2 propan differing from *BAL* only in the position of the seco —SH group, is much more toxic. By the use of homologous series of dithiols Whittaker[43] was able show that there was a fall in the effectiveness dithiols with compounds which would be expected make a ring containing seven atoms, thereby su porting the ring hypothesis.

Medical Applications

These aspects are now being pursued in Brita under the ægis of the Medical Research Coun (*BAL* was initially described as *OX* 217 for securi reasons). Treatment of arsenical accidents in t factories with *BAL* ointment proved very successful It was early realized that there were possible app cations against both the toxic complications therapeutic arsenical drugs, and inunction therapy w used by this group in 1943. These aspects develop much more rapidly in the United States, where su cessful inunction treatment of arsenical (*D M*) d matitis was early obtained. This method was i mediately superseded by the preparation in t United States of an ampoule (using as a vehi 10 per cent benzoyl benzoate in arachis oil) whi was suitable for intramuscular injection of *BA* This has been extensively used, both in the Unit States and also under our direction in Britain. Ve favourable results were reported from the Unit States in the treatment of the complications arsenical therapy such as dermatitis and encephalit Of a series of thirty cases in England, some we treated by inunction early in 1943 and the later on with an ampoule following the U.S. formula, after t became available; it was believed that some 50 p cent cases had responded to the treatment favo ably[45]. This is much better than any other treatm so far tried, but a final judgment will have to based upon a larger series of cases. Based up American experience, initial dosing can now be high as 4 mgm./kilo *BAL* at four-hourly interva has been found both in Britain[46b] and the United ates that after recent dosing with 'Mapharside' the cretion of arsenic in the urine is definitely increased administration of *BAL*; after longer intervals m dosing with the arsenic compound, however, it more difficult to pick up any extra differences due the *BAL*, which are masked by the large daily riation in arsenic excretion usually present. This s well illustrated in the urines of the patients alysed by the Edinburgh group[45]. Enzyme experi- nts have shown that *BAL* will protect against the xic effects of therapeutic arsenicals[38]. The com- und of *BAL* and 'Mapharside' appears slightly more sociable than that with lewisite and requires the esence of excess of *BAL* for its stabilization and duction in toxicity to rats[47]. An important indica- n for treatment has been raised by Cameron, rgess and Trenwith[48]. Animals with renal damage oduced by injection of uranium acetate showed no fference in their response to large doses of *BAL*, hereas animals with livers damaged by carbon trachloride showed toxic signs. This suggests that patic damage is a contra-indication to the use of *AL*.

Finally, arising out of an investigation on colour actions, it was found that very stable and un- ssociable metal compounds were formed with thiols[32,39]. This observation initiated tests of thiols in other cases of metallic poisoning, an aspect the work which is now being actively explored th in Britain[49] and in the United States.

Acknowledgments

It is almost impossible in a short space to thank l those who have contributed in various ways to e success of this investigation. The work gained y regular discussions in the Department with the ustard gas group (J. St. L. Philpot, A. G. Ogston nd E. Holiday); much is owed to the co-operation f the permanent staff at Porton, among whom may e mentioned Surgeon Capt. Fairley, and also to Prof. . R. Cameron. Without the support of Mr. J. avidson Pratt and his colleagues at the Ministry of upply during these years and especially when the wer biochemical views were on their trial, nothing uld have been accomplished; we have also received lp and valuable criticisms from their various ientific advisory committees. Our thanks in this epartment are due to the Nuffield Committee, xford, for grants in part aid of this work. We are rateful to the Chief Scientific Officer, Ministry of upply, for permission to publish the facts.

SCIENCE AND ETHICS

By Prof. JOHN A. RYLE

Professor of Social Medicine, University of Oxford

THE development of methods and techniques for the release of atomic energy and the actual employment of the atomic bomb have demonstrated to the world at large, not only the immense and ever-expanding potentialities of science, but also the immediate power which lies in the hands of men of science. Hitherto the majority of those concerned with the fundamental sciences have not been directly concerned with the exercise of power but with the pursuit of knowledge. With the vast extent of their material power revealed, it now becomes both possible and imperative for them to discover the extent of their moral power and, taking their stand on ethical grounds, to indicate the full part which they are willing and able to play in human affairs and also the conditions under which they will in future agree to the conscription or hire of their minds. In order that they may do this, two things would seem necessary. First, recognizing that their work and its needs ensure for them certain privileges and that these very privileges have hitherto compelled a certain detachment from human affairs, they must more generally accept that they have other important functions as leaders in world citizenship, functions which are to-day increased in their importance by virtue of their new achievements. Secondly, they must surely, in their local, their national and their international assemblies and in the course of their teaching, consider and affirm at the earliest possible date, and frequently thereafter, what they consider to be their particular duties and their rights.

The man of science has always been influenced by certain ethical ideals connected with the conduct of his science and his association with his fellows. Intellectual integrity and freedom, the absolute necessity for veracity, and precision, the sharing of new knowledge, the obligation to publish important findings, the recognition of priority where priority is due—all these, together with his perfections of method, have made his discipline a thing apart, and the disciplines of some other professions seem poor by contrast. But he has not yet evolved a clear or comparable ethical code in respect of the relations of his science and his discoveries to the community and to the race.

We have an important precedent for the formulation and common observance of a more general ethical code by one profession. Medicine, a parent of the sciences, from the days of Hippocrates (whose famous *Oath*, together with the *Precepts*, *Decorum*, *Physician* and *Law*, defined the duties of the physician) has been constantly directed by a very binding and widely effective ethic relating not only to the conduct of its science and of its scientists and practitioners to one another, but also to the particular duties which medical men owe to man. Now it is obvious that the uses of medicine have been primarily and purposefully humane. Even so, the physician in all ages and in association with his particular powers has had plentiful opportunities for dubious or harmful actions of many kinds and for withholding or bartering useful knowledge for personal ends. It was these opportunities that made his ethical code necessary.

To-day we realize that all the other sciences are literally the physicians of man's future, that they could in time prevent or cure a thousands ills, but that they too have plentiful opportunities for harm. Is it too much to ask of the scientific fraternity in all countries that they should unite now in recognition of the absolute necessity for a declared ethical code and that they should proceed to its formulation? A provisional charter of rights and duties, outlined and circulated, let us say, by the Council of the Royal Society in Great Britain, and modified and agreed by the academies of science of other nations, discussed in all the learned societies and with students, and finally made public, would not only be received as a historical event of unique importance, but also would go far to restore a declining faith in the intelligence and prospects of man. It might, furthermore, do much to arrest the present deterioration in international sympathies and help both to neutralize the hostile suspicions of statesmen and to retard the schemes of the now dependent general staffs. For the declaration of such an ethical policy (however difficult it might be to implement at first) could mark the beginning of a rule of reason and would, in essence, constitute a powerful plea for non-co-operation with industries and governments in all war-like and ant social preparations and equally an insistence on the fuller co-operation in scientifically proved measur for human betterment. The engineer, the technicia and the public have, perhaps, a right to look f leadership to the accepted leaders of thought i matters of such moment. Morality and social servi concern us all, and, whenever possible, should b related to our more special tasks.

Let us return, for illustration, to the ethics of th physician. Medical men are ordinary men wit ordinary human frailties. We know that there a occasional back-sliders among them and that, whe their fault is grave, they become subject to stron disciplinary action at the hands of the profession own tribunals. But we know also that, by and larg medical men have maintained high standards throug the centuries and that their individual and corporat morality ensures for them the trust and respect the community. They do not engage in profit fro the sale of medicines; they seek no material rewar from their discoveries; they care for the sick an wounded enemy in war-time; they have the good the individual, the community and the race in min whatever their branch of the profession may b Accepting, as they do, the principle which was condensed in the Hippocratic injunction "to help, or a least to do no harm", it is difficult to believe that an responsible group of physicians or pathologists coul be found in any country to subscribe to bacteri warfare, even if they were able to discover an effectiv method without repercussions, and even if th strongest pressure were brought to bear upon the by a government and its military leaders.

Ethically speaking, is there anything to choos between an organized cholera epidemic and an atom bomb? With the Second World War behind us an a general agreement that a Third World War, employing atomic weapons, would be the end of ou civilization, what case—whether ethical or practic —can the physicists put forward for any new co-operation directed specifically towards the development of these weapons? International agreemen and controls may accomplish much; but they a not enough. The fullest possible opportunity an expression must also be given to moral decisions, an these should be based on finite knowledge as well a ideal thinking.

What has been said has reference to the prese and the future. It implies no criticism of the remarkable contributions of our men of science to the victorious prosecution of the War. It may be assume that the military decision to drop the two bombs o two densely populated cities, instead of on an unpopulated 'demonstration' area of Japanese territory, wa not the choice of the men of science and may well ha been opposed by them. But now that they know th potency of the new material agencies and how the discoveries may be utilized, can they do otherwi than decline to be further associated with militari preparations? Anxious as they must be "to help, o at least to do no harm", should not their futu direction of applied atomic research be exclusivel towards the development of its beneficent and productive uses? And, is there any body of men mo likely than they are to reach international agreeme on a decision of this nature?

Ethical ideals and policy should not, however, b considered only in relation to possible future war The scientific worker's mind may be conscripte through economic necessity or otherwise hired, n

ly for secret *ad hoc* undertakings under government,
ut also for the ends of private profit and sometimes
r purposes which he cannot, in his heart, approve.
his liberty and his right to communicate or publish
e restricted by an employer, he must deny a part
his already accepted ethical code. If he is party
the production of over-costly materials which
ould benefit the whole community, he must deny
e humanist morality now required of him.

So powerful, however, is the position of men of
ience to-day and so considerably has their prog-
ostic ability increased, that they could become, in
me measure, the conscience as well as the technical
lvisors of the State. In the face of a concerted
eclaration of rights, the exploitation of those younger
en of science who cannot find a place in academic
ork and whose skills could, under just conditions,
usefully employed, would be made at once more
fficult and eventually impossible.

In a more positive sense, right actions in a social
gard could be more frequently sponsored by the
uthoritative pronouncements of important scientific
oups. Social responsibility should to-day extend to
e effective instruction of the community and of
ntral, local or colonial governments whenever
olicies touching the public weal are in question and
pecially when full scientific support for a particular
eneficent policy is forthcoming. Here, for example,
edical science could already make a larger con-
ibution. Nutritional physiology had for some time
tablished the basic human requirements, and yet it
ok a world war to ensure for the working people of
reat Britain an equitable distribution of necessary
ods. We still accept in England an annual death-
ll of between one and two thousand children from
ovine tuberculosis and much other sickness and
isability due to contaminated milk. The occasional
rotests and individual writings of physicians and
ygienists have been educationally insufficient to
ounter ill-informed opinion and to secure necessary
gislation for the universal pasteurization of milk for
uman use.

The full responsibilities of the science teacher to
is students also call for thoughtful revision. The
te Prof. J. S. Haldane, in his Gifford Lectures (1928),
oncluded an argument concerning the fundamental
haracter of psychological or humanistic knowledge
ith the following sentence: "It follows that the
asis of a sound education must be humanistic, and
hat even the teaching of abstract sciences such as
athematics or physics should, through the history
f these sciences or in other ways, be connected with
uman interest".

Seventeen years later an alliance of science and
umanism in the teaching of our schools and univer-
ities has become more than ever necessary.

Ethical ideas and practice, phenomena peculiar to
uman societies, will in due course be themselves
ubjected to more intimate and scientific study, as
e have been lately reminded by Julian Huxley in
is Romanes Lecture (1943), by Waddington and
thers. But in the meantime we have evidence on
ertain major issues which compels us to assume right
f judgment. Moral thinking and teaching are not a
rerogative of the philosopher and the theologian.
or can they thrive in dissociation from other
pecific intellectual activities. Fundamental physical
tudies and humanistic studies can no longer proceed
fely in complete separation. The Good, as well
s the True, has become a necessary objective of all
ience.

OBITUARIES

Prof. N. I. Vavilov, For.Mem.R.S.

NEWS has recently been received of the death in the Soviet Union of Nikolai Ivanovich Vavilov. The circumstances are not precisely known, but the time was after December 1941 and the place probably Saratov.

Vavilov was born in 1885 and was the son of a textile manufacturer. His sister was a medical woman and died of typhus during the First World War. His brother is a physicist and is now president of the U.S.S.R. Academy of Sciences. He had two sons.

In 1913 and 1914 Vavilov worked with Bateson at the newly established John Innes Horticultural Institution. There he published a paper revealing one of the main lines his thought was to follow: "Immunity to Fungous Diseases as a Physiological Test in Genetics and Systematics exemplified in Cereals" (*J. Genet*, **4**, 49–65). His idea was Darwinian, but its development was genetic in the modern sense. Its novelty depended on his taking the practical problem of host and disease as seen by the pathologist, and turning it upside down.

Vavilov returned to Moscow in August 1914, not without mishap. His valuable experimental materials were lost with the S.S. *Runo*, which struck a mine on the voyage home. During the War, he began the second of the important lines of his life's work—namely, exploration for cultivated plants. He visited Persia and the surrounding countries in 1916, principally in search of the cereals, the systematic relationships of which he had already examined experimentally.

In 1917 he went as professor of agriculture, botany and genetics to Saratov. Here he wrote the paper which provides the third line in the origin of the new methods combining systematics and genetics which he was to adopt, "The Law of Homologous Series in Variation" (*J. Genet.*, **12**, 47–89). Finally, in 1921, he was picked by Lenin for a post of unexampled opportunity. He found himself, at the age of thirty-six, president of the Lenin Academy of Agricultural Sciences and director of the Institute of Applied Botany.

Inspired by his own enthusiasm, and by Lenin's determined policy, Vavilov set up more than four hundred research institutes and experimental stations in the course of a few years. Several of these had as many as two hundred research workers, and the total number of their staffs in 1934 amounted to 20,000. His journal, the *Bulletin of Applied Botany, Genetics and Plant Breeding*, with its comprehensive surveys and its numerous supplements, became a leading international organ of publication in its field.

In these days it was a remarkable sight to see Vavilov at work in what he now called the Institute of Plant Industry, the palace which he had converted to his use. Here he would be, in his shirt sleeves, sprawled over a map of the Soviet Union covering the floor of his office, busy distributing and arranging his staff and stations. No less remarkable was the experience of flying with him from one to another and watching his vigorous, confident and cheerful handling of the machinery he had created and of the people who were working it. Wherever he went he took sunshine and courage. Nicolas III (as he playfully called himself in contrast to the statue across the road) certainly got things done.

In spite of these vast administrative duties, Vavilov found time to direct the precise scientific methods to be followed in his institutes, especially in regard to economic botany and the question of immunity to disease in plants. He set to work to make thorough collections of varieties of economic plants over the whole of their ecological range. These were to be the raw materials for synthesizing new types for specialized regions. During the years 1923–31 he organized and carried out, often alone, a series of expeditions to what he regarded as the important economic plant regions of the world—to Afghanistan, Abyssinia, China, Central and South America—to collect material of all economic plants of interest to the Soviet Union. As an example of the scale on which the work was planned, no less than 26,000 varieties of wheat alone were obtained and kept in cultivation at Leningrad. At the same time he made the Soviet Union itself the chief ground for similar studies of the origin and distribution of varieties of livestock, horses, cattle, reindeer, and so on.

These collections were also to be the raw materials of new theories, theories on the origins of cultivated plants which he set out at the Fifth International Genetics Congress at Berlin in 1927, and later embodied in his "Theoretical Bases of Plant Breeding" (1935, Russian text). His crucial idea was derived from plant systematics. It was that the geographical centre from which a species of cultivated plant spread was marked by the greatest genetic diversity and also the greatest concentration of dominant genes. The meaning and validity of this contention have been disputed on both special and general grounds. Its value, however, was, and remains, in its effect in making possible the combined and rigorous systematic and genetic (including, of course, cytological) treatment of variation within species of cultivated plants. In theory, Vavilov marked the first great advance on De Candolle; and in practice he laid the foundations of all future improvement of crop plants. His own potato collection, for example, led to the establishment of the British Empire Potato Collection on which potato breeding is now being based in Britain and elsewhere.

Vavilov himself led the expeditions to Abyssinia and South America. The Abyssinian expedition was his first. It was economical; Lenin allocated to it the small grant of £1,000. It was also arduous; for six weeks in the mountains Vavilov did not remove his overcoat. He ate native food, slept on the floor of native huts and most of the time he suffered from typhoid or dysentery.

His unsleeping mind, his untiring body, his ambitious plans, even his flamboyant showmanship, were all Napoleonic in character. But his intellectual integrity was never in doubt. Whenever he met another man of science for the first time he would ask, "What is your philosophy?" In other words, "How do you approach your problems?" Vavilov himself approached his problems in a spirit of perpetually youthful inquiry and optimism, never forgetting however, as he used to say, that "Life is short". His attitude is well illustrated by a quotation from his last publication (in "The New Systematics", Oxford, 1940). "We are now," he writes, "entering an epoch of differential ecological, physiological, and genetic classification. It is an immense work. The ocean of knowledge is practically untouched by biologists. It requires the joint labours of many different specialists—physiologists, cytologists, geneticists, systematists, and biochemists. It requires the international spirit, the co-operative work investigators throughout the whole world. . . . do not doubt that the new systematics will bring to a new and better understanding of evolution, t great increase in the possibilities of governing t processes of evolution, and to great improvement our cultivated plants and domestic breeds of anima It will bring us logically to the next step; integrati and synthesis."

Already, however, after the notorious genet controversy at the end of 1939, from which t Lysenko school emerged successful, Vavilov h apparently lost his executive positions, and, in sp of many attempts, his friends failed to communic with him. His work and his workers seemed to fa away; and, when Leningrad came to be besieg the residue of his collections was eaten by t famished people. But though, in later years, he w thought little of by the Soviet authorities his fa abroad steadily increased. He was asked to president of the International Congress of Genet in 1939—an honour which he had to renounce, aft first accepting, when the Russians decided to ta no-part in the Congress. In 1942 he was elected foreign member of the Royal Society.

Vavilov spent all his life collecting and observi and arranging facts and ideas, many of them outsi the field of science. In his travels he was helped being a good linguist. With the same enthusias with which he studied their agriculture, he follow the customs, the music and the arts of the peopl he journeyed among. Physically he was of stoc build and dark complexion, with a Tartar cast countenance. A host of friends in Europe a America will lament his death. They are not like to forget his Robesonian depth of voice, his Falstaffi breadth of gesture. But science at large will rememb his achievement, an achievement that survives h personal disaster.

S. C. Harland.
C. D. Darlington.

Dr. L. A. Borradaile

Lancelot Alexander Borradaile, who died hospital on October 20, aged seventy-three, w known to most medical and zoological students of t last twenty-five years. Wherever English is spoke he was the author of their first text-book, "Manu of Zoology", and a shortened form when medic examinations became more strenuous. He was t son of a city merchant in the African trade who family came from the Lake District. Educated Blackheath and Felsted, he entered Selwyn Colleg Cambridge, receiving a scholarship in 1893 when obtained a first class in the Natural Sciences Trip a feat repeated in Part II, 1894, in spite of poor heal which prevented his taking part in games; t caused a certain neglect in his schools and he beca shy, which in his social life greatly hindered him.

In 1895, Borradaile commenced to demonstrate the Zoological Laboratory, Cambridge, where worked under Bateson on the variation in Crustac In 1899 he accompanied me round the coasts Ceylon and to Minikoi; he had already studi Willey's Stomatopoda and discovered the mar development of the coco-nut crab. In the tropics settled down to work on the biology, physiology a anatomy of land Crustacea, now regarded as classical research. This was followed by his thoug the varieties and species in the decapod crustaceans which he refers to "varietal characters" and ariations within a homogeneous species or variety". er this he published a series of memoirs ending in form of their classification. He regarded the crabs a true group with a common phylogenetic origin ough the Dromiacea. The attempt to show that main divisions of the Brachyura were ecological vell as morphological groups, based on adaptations swimming, sand-burrowing, sponge-carrying, sking' and so forth was very interesting and minating. This was followed by a further con- eration of land forms and the relationships of tain prawns, particularly the Pontoniinæ from the *lark* Expedition. He summarized some of his ws in two important papers in the *Annals and gazine of Natural History*. In 1922 he was awarded degree of Sc.D.

n 1908 Borradaile was appointed University monstrator in animal morphology and in 1910 turer, retiring in 1937. It was his own choice to cialize in the advanced teaching on invertebrates: divided his groups into full courses extending ough four terms in two years, choosing Crustacea l general questions relating to them, starfish, tochordates, protozoans and odd forms. He was ays clear, concise, and there was little original rk which was not included. He was at his best in practical classes, into which he developed in himf and his pupils an enthusiasm often started by ne question.

Borradaile had been taking his share of extra-mural turing for twenty years, when he published "The imal and its Environment", 1923, a subject which chose for lecture courses especially in East Anglia d to the Forces during the War of 1914–18: it gave to many a delightful hobby wherever they might reside, but the book was spoilt to science students by the publishers' view that the best form of illustration was by the reproduction of text-book and other well-known figures.

Dr. Borradaile was in succession lecturer, dean and then tutor of Selwyn College, and he helped both in his College and in the University during the war period, 1939 onward. He was offered scientific preferment, but his College held the first place in his affections. He was a most conscientious tutor, following the careers of his students, domestic and otherwise, often helping financially those in need. He was a wise counsellor, though his shyness prevented close friendships. He was very proud of being a freeman of the City of London and on the Livery of the Drapers' Company. He liked travel and he had a deep appreciation of pictorial art. In termtime in his later years his hobby was gardening—his dahlias 15 ft. high, fed from a compost heap, were known to all passers-by. In him Cambridge loses a notable figure ever helpful in all its activities.

J. STANLEY GARDINER.

WE regret to announce the following deaths:

Dr. Frank M. Chapman, emeritus curator of ornithology in the American Museum of Natural History, aged eighty-one.

Dr. J. F. Tocher, formerly lecturer in statistics in the University of Aberdeen, and consulting chemist to the Highland and Agricultural Society of Scotland since 1912, on November 8, aged eighty-one.

Lady Woolley, who took part with her husband Sir Leonard Woolley in archæological work at Ur of the Chaldees and elsewhere, on November 8.

NEWS and VIEWS

ience and Ethics

WHILE not agreeing with all the statements made Prof. J. A. Ryle in his plea for a more ethical proach to matters scientific (beginning on p. 619), feel that a suggestion that men of science should t together and devise some form of charter to ide their future activities is timely. Charters for n of science have been put forward for their con- eration on previous occasions; but there is one dition which seems to us to be imperative. That the charter must receive the support of, and be noured by, men of science in all countries; this es not seem likely of achievement if we have with men of science who are working under any kind political regime where they are subject to political ntrol and even orders. Absolute scientific freedom *every* country is essential if any form of charter to have the desired effect. Readers of *Nature* will all a suggested "Ethical Declaration for the Times" men of science by Mr. L. L. Whyte published ring the disturbed times of 1938 (*Nature*, **141**, 827; 38). That declaration read as follows:

DECLARATION

I am the inheritor of the tradition of civilization which s proved more lasting than empires. Whenever I use language or the products of science I unconsciously pay mage to the countless men for whom no sacrifice was great in the struggle to develop the human mind and ablish the truth. Toleration and freedom are the heart of this tradition; for individual thought and love of truth are the basis not only of science, but also of justice and of civilization.

I declare my loyalty to this tradition, my belief in the freedom of the individual to develop his talents for the enrichment of the community, and my conviction that man's community is now the whole human race, within which each nation must play its characteristic part. The natural balance between personal freedom and the proper demands of society, which is the life and health of civilization, is to-day doubly threatened; in certain societies by the denial of freedom and in the democratic countries by the irresponsibility of individuals. In the face of this threat:

I pledge myself to use every opportunity for action to uphold the great tradition of civilization, to protect all those who may suffer for its sake, and to pass it on to the coming generations. I recognize no loyalty greater than that to the task of preserving truth, toleration, and justice in the coming world order.

College of Aeronautics: Appointment of Mr. E. F. Relf, C.B.E., F.R.S.

THE recent announcement that Mr. E. F. Relf, superintendent of the Aerodynamics Division of the National Physical Laboratory, has been appointed principal of the newly founded College of Aeronautics, will interest all those who are concerned with the well-being of British aeronautics. The purpose of the College, as defined in a recent report published by H.M. Stationery Office, is to provide a high-grade engineering, technical and scientific training in aeronautics for selected students to fit them for leadership in industry and civil aviation, in the Services and in education and research. The College has a governing body of its own, representative of all the interests concerned. Nevertheless, the principal and his staff must bear the responsibility for setting the standards and establishing tradition, especially in the early days. Mr. Relf served an apprenticeship for five years in Portsmouth Royal Dockyard. In 1909 he was awarded an open Royal Exhibition tenable at the Royal College of Science, where he won the Tyndall Prize for physics in 1910 and obtained the diploma of the College in 1912. He was appointed to the staff of the National Physical Laboratory in 1912, and thirteen years later was made superintendent of the Aerodynamics Department.

During his early years at the National Physical Laboratory, Mr. Relf was engaged on aerodynamic researches and, under Stanton, Bairstow and Southwell, made a noteworthy contribution to the establishment of the international reputation of the Department. One of his outstanding achievements at that time was the design of the balances and controls for the compressed-air wind tunnel, a very powerful research equipment which enables air-flow problems to be studied over a very wide range of Reynolds numbers. Owing to the high pressure in the tunnel (up to twenty-five atmospheres) direct operation of the balances is not possible: they must either be automatic or operated from outside the tunnel. After a great deal of thought, Mr. Relf decided to base the design on the principle of the Kelvin current balance and in such a manner that an observer could measure, at any moment, the forces acting on the model in the tunnel. The successful operation of the balances under the stringent conditions existing in the tunnel is a testimony to his skill and foresight. After his promotion to superintendent, administrative duties and committee work made an ever-increasing demand on his time, but he could always find time to give guidance and sound advice to members of his staff. Mr. Relf is a member of the Aeronautical Research Council and of several committees of the Ministry of Aircraft Production. He has always been keenly alive to the value of a close contact between research and industry, and he has taken every opportunity to get first-hand information on the problems of aircraft firms. The best wishes of his many friends will be with him in the tasks that await him at the College of Aeronautics.

Chair of Pharmacology, College of the Pharmaceutical Society

Dr. G. A. H. Buttle has been appointed to the chair of pharmacology at the College of the Pharmaceutical Society, in succession to Prof. J. H. Gaddum, who now holds the chair of pharmacology at the University of Edinburgh. Prof. Buttle returns from a long and varied experience in the Army, in which he held the rank of lieut.-colonel, R.A.M.C. He served for six years as officer commanding Base Transfusion Unit and adviser in resuscitation with the Middle East Forces and later with the 21st Army Group. Previous to the War, in conjunction with Henry, Trevan and Stephenson, he published work on chemotherapeutics from the laboratories of the Wellcome Foundation, including much work on the antibacterial action of sulphanilamide and allied substances in streptococcal infections. In conjunction with Colebrook and O'Meara he demonstrated the inhibitory effects that sulphanilamide compounds had on bacteria out the body. During the War, in conjunction v Lieut.-Colonel G. Mitchell, he published invest tions on the treatment of infected war wounds v powder of sulphanilamide and derivatives of acrid and several articles on blood transfusion for ser purposes. As director of the Pharmacological L oratories in the College of the Pharmaceut Society, he will be able to continue the work of B and Gaddum on biological assays, and will undou edly be a great asset to the team of research worl already engaged on the chemical aspects of chemo therapy.

Agricultural Economics Research Institute, Oxfo Appointment of Prof. A. W. Ashby

Prof. A. W. Ashby, professor of agricultu economics at the University College of Wa Aberystwyth, who has recently been appoin director of the Agricultural Economics Resea Institute, Oxford, in succession to Dr. C. S. Orw was a scholar of Ruskin College, Oxford, and la was the first holder of a research scholarship at Institute to which he is shortly to become the he After a period of study at the University of Wiscons he was attached to the Food Production Departm of the Ministry of Agriculture during the First Wo War, returning afterwards to the Institute as sen assistant. Appointed to Aberystwyth in 1924, created the Department of Agricultural Econom there, and began a study of the economic proble of farming in Wales out of which has developed advisory service, particularly in connexion with t co-operative movement, which has proved of first-ra importance to Welsh farmers.

The chair of agricultural economics at Aberystwy to which Prof. Ashby was elected in 1929, was the fi in the subject to be created in Great Britain, and educational work has attracted students from ma parts of the world. As a member of several roy commissions and departmental committees, t National Council of Agriculture and the Agricultu Wages Board, his experience and knowledge ha been freely drawn upon by the Ministry of Agricultu and by agricultural organizations in England a Wales. Prof. Ashby is entering upon his new dut at a very critical time in the history of agricultu when the artificial prosperity induced by war co ditions will shortly pass, and the industry will ha to establish itself upon a peace-time footing. such conditions, few better fitted than he could found to direct research into the problems wh confront those whose interests and livelihood are the land, and to play a part in framing the educati which university students, both undergraduate a postgraduate, will need.

Adam Hilger Ltd.: Research and Developmen

Group Captain A. C. Menzies has been appoint controller of research and development to the firm Adam Hilger, Ltd., and commenced his duties November 14, succeeding Mr. F. Twyman in th capacity. Mr. Twyman continues with the firm managing director and technical adviser. Dr. Menz saw active service in the War of 1914-18 as a seaple pilot in the Royal Naval Air Service, and af graduating from Cambridge had appointments physics at the University of Leeds, Univers College, Leicester, and University College, Southam ton. At Leicester he inaugurated the Physics Depa ment in the newly formed College, and at Southam he held the chair. In December 1944 he was pointed to the chair of physics at University lege, Swansea, the appointment to take effect er demobilization; but by the courtesy of the lege was released from this and enabled to join am Hilger, Ltd., where his specialist knowledge administrative experience will be of particular ue. During the War he was in charge of operational earch at the Air Ministry and was deputy director science and deputy scientific adviser; and, since ember 1944, when Sir George Thomson retired m the post, he has been acting as scientific adviser, ding a peace-time appointment. He has specialized spectroscopy, first in atomic spectra, later in the man effect.

ence in the United Nations Organisation

MEMORANDUM by Mr. Guy B. Gresford, Australian ntific research liaison officer in London, entitled e Scientist and the Economic and Social Council", r referring to the major part played by the man science in the Second World War and to some of achievements which have been among its most king features, points out that, particularly among United Nations, scientific workers were called t the highest level in the prosecution of the War, help in formulating as well as in the execution of ns. Mr. Gresford's memorandum argues that it is as important that the man of science should y his part in the international organizations igned to ensure economic and social progress for nkind as a whole. His place in the functional anizations is obvious; but Mr. Gresford points out t it is equally necessary for him to be included hin the scope of the Economic and Social Council, ch, in securing expanding economic and social gress, must rely largely on scientific and technical owledge. In planning for the future, the Council st refer to scientific experts, not only to ascertain present state of knowledge as it affects a parlar project, but also to attempt to forecast the gress likely to be made in the future before effect be given to the plans. Mr. Gresford illustrates argument by reference to the interaction of rubber duction in tropical areas to the manufacture of thetic rubber, and the relation of long-term hydrotric schemes to the development of atomic energy. Accordingly, Mr. Gresford urges that the place of scientific worker on the Council should be that of ull working partner; only thus can the Council e the longest view and ensure that changes brought ut by scientific developments occur gradually and hout deleterious effects. Interchange between the nomist, the social worker and the man of science st be complete and at all levels. The Council will uire the best scientific advice that it is possible obtain, and should have at its call the leading ntific men of all fields. For this purpose, Mr. sford, like Dr. J. Needham (see *Nature*, 156, 401, ; 1945), suggests the establishment of a standing ntific commission to advise the Council on all ntific matters, as well as a small permanent ntific secretariat, and technical advisory comtees of distinguished men of science to deal with ticular projects outside the scope of the interional functional organizations. The standing mission would consist of twelve to fifteen members h an initial period of service of, say, three years, the secretariat would be composed chiefly of ly young scientific workers with an administrative t, seconded for a few years from national scientific organizations. If the Council established regional offices in connexion with the specialist organizations of the United Nations, Mr. Gresford suggests that the scientific side might establish an international liaison service, but on rather more modest lines than those proposed by Dr. Needham.

The Industrial Research Bill

THE Industrial Research Bill introduced recently into the House of Lords by Lord Barnby is intended to improve and strengthen the existing machinery for forming and operating industrial research associations in Great Britain. It is an 'Enabling Bill' under which the majority of interests in any industry can, if they so desire, put forward to the Board of Trade a scheme for operating a co-operative industrial research association. The Board of Trade will approve the scheme if adequate arrangements have not already been made to undertake the scientific research provided for by the scheme, if the scheme is in the national interest and if the promoters appear to represent at least half of the industry concerned, but the scheme will only operate if after such approval at least 75 per cent of the firms in the industry vote in favour. Special minority interests will be permitted to obtain exemption if they have already made their own adequate arrangements for scientific research, if they are too specialized to derive any benefit from a research association or if payment of contributions would involve serious financial hardship. The levy is not to exceed one per cent of the turnover or revenue of any firm. While the Bill does not deal with the scale of Government financial contributions towards the funds of the research associations, it is assumed that State aid would be forthcoming on a generous scale, in view both of the present arrangements and categorical assurances as to the intention of the Government to give the maximum support to scientific research and technical development.

Relics of Peking Man

ACCORDING to a New York correspondent of *The Times*, American agents have recovered from the Imperial University, Tokyo, crude tools, a carved tooth, jewellery and other objects looted by Japanese men of science from the cave at Choukoutien, in China, of the Peking man (*Sinanthropus pekinensis*). They will be returned to the National Geological Survey of China. Letters seized with the relics disclosed that the Japanese were never able to discover in a three-year search where the Chinese had hidden the skeleton remains of *Sinanthropus pekinensis*.

Rh and Blood Transfusion

THE future of the blood-transfusion services has been the subject of much anxious thought among those who have helped to create and man them and also among the general public. One important aspect of their future is discussed in a leading article in the *Lancet* (112, July 28, 1945). This is the possibility that *Rh*-positive blood may be transfused into an *Rh*-negative individual. The first transfusion of the *Rh*-positive blood causes the development of anti-*Rh* agglutinins in the serum, so that a subsequent transfusion of *Rh*-positive blood may produce an incompatibility reaction exactly similar to that which occurs when Group *A* blood is transfused into a Group *B* person, namely, hæmolysis of the incompatible blood cells and possibly jaundice or hæmoglobinuria. This reaction may be mild, severe or even fatal. Further, an *Rh*-negative woman may have been sensitized by having an *Rh*-positive baby, or by a transfusion of *Rh*-positive blood; if she then has an *Rh*-positive child, there is increased risk of erythroblastosis or of an allied condition in this child. Also, if an *Rh*-negative mother has an *Rh*-positive child and is sensitized by this child, her first transfusion of *Rh*-positive blood may cause an incompatibility reaction. American work has shown that this *Rh*-sensitivity may last for eight to twenty-two years. In addition to this, anti-*Rh* agglutinins cannot yet be always detected in the blood. R. R. A. Coombs, R. E. Mourant and R. R. Race have, however (*Lancet*, 15, July 7, 1945), described a new method of detecting weak and 'incomplete' *Rh* agglutinins in the blood (cf. also Coombs, R. R. A., and Race, R. R., *Nature*, **156**, 233 (1945) and the discussions by A. J. McCall and S. Holdsworth in *Nature*, **155**, 788 (1945) of hæmolytic disease of the newborn due to the antibody *St*, H. S. Baar (*ibid.*, 789). on the Race–Wiener test in hæmolytic disease of the new-born, and G. Plaut, M. Barrow and J. M. Abbott (*Brit. Med. J.*, 273, Sept. 1, 1945)).

The further difficulties of this problem and the measures to be taken to avoid the risks concerned are discussed in the *Lancet* (*loc. cit.*). Obviously they are matters for the expert, and everyone will support the conclusion that blood-grouping, especially when it is related to maternity work, can no longer be left in the hands of an individual pathologist, who may be employed upon this work only for part of his time; nor can supplies of *Rh*-negative blood be left to small panels of local donors. The post-war blood-transfusion service will have to be very carefully organized, not only to meet the known risks involved, but also to provide research facilities and personnel on a scale adequate to the future public importance of the whole problem. Blood-transfusion sources available during the War have provided one of the outstanding examples of the beneficence of scientific discovery. It would indeed be an indictment of our civilization if, now that peace has returned, we failed to give this particular service every encouragement and facility possible.

Religious Instruction in Schools

A Committee of Representatives of the Joint Conference of Anglicans and Free Churchmen, the Association of Education Committees and the National Union of Teachers has prepared a pamphlet entitled "A National Basic Outline of Religious Instruction" (London: National Union of Teachers, 1945. *2d.*). The pamphlet calls to mind an article bearing the above heading which appeared in *Nature* of November 14, 1942. Much has happened since then, but the article still stands as an explanation of the reasons why a scientific journal should in its own way deal with the problem of religious education. In particular, we retain the conviction that, after all is said and done, the psychological core of the problem lies in the relation of the teacher and the pupil, and that unless one can trust the teachers no precautions will avail. Choose the teachers carefully, train them adequately, and then trust them. The liberty of the well-prepared teacher is the essential condition.

The pamphlet is not a syllabus, but a broad 'outline' of the kinds of material that may by common consent be used in the making of a syllabus. The outline is quite unique in being national, not local (a national syllabus is an absurd idea, but a national outline is another matter). It is unique also in having been prepared by a committee in which teach were on equal terms with religious bodies and edu tion authorities. The outline repeatedly states t the true interests of the children have ever b paramount in its production. It might be ad in the same breath that the liberty of the teache the only way to secure the true interests of the ch ren. The idea of the broad outline, which ma no pretence whatever to be a syllabus, suitable any school, any teacher, and any social environm has enabled the committee to make suggesti especially for the older pupils, in directions that wil welcomed in many quarters, such as comparison Christian beliefs with those of other religions, Bible and science, miracles, and problems of pers and social ethics. "The spirit of enquiry," says Committee, "should be welcomed, stimulated fostered." That one sentence sums up the reas for giving strong approval to this basic outline.

British Bryological Society

On September 12 the British Bryological Soc held its first meeting since June 1939. It announced that, during the War, the Society eighteen members, including H. N. Dixon, P. Allo W. E. Nicholson, H. H. Knight, C. H. Binstead H. G. Jameson; new members during the same pe total nearly forty. It has not been possible to re contact with more than a few of the Continental m bers. It was decided to have a distribution of sp mens during the coming winter, and the time of next meeting was fixed for about Easter 1946, wit second one to be held during the winter follow Suggestions concerning biological observations bryophytes which might be usefully undertaken members were put forward and considered. advisability of publishing new editions of the Cen Catalogues of British Mosses and Hepatics was to the decision of a special committee. On Sept ber 13, Dr. S. Wyard led a party of twenty-ei members on a ramble in the neighbourhood Newlands Corner in Surrey. Although not a district bryologically, it yielded a few interest plants, including the rare *Dicranum strictum* Schlei a recent addition to the flora of Britain. In evening the party gathered at the South Lon Botanical Institute to hear Dr. P. W. M. Rich give a talk on "The Growing and Cultivation Bryophytes". Those interested in mosses or li worts can obtain particulars of the objects of Society and conditions of membership from secretary, Mr. A. Thompson, 23 Regent Cresc Skipton, Yorkshire.

Announcements

Dr. Herman Shaw, keeper in the Science Muse has been appointed director and secretary of Museum in succession to Colonel E. E. B. Mackint who will retire on November 30.

Dr. J. S. H. Davies, formerly of Imperial Chem Industries, Ltd., has taken up his duties as dire of research of the British Schering Research Insti in succession to Prof. D. H. Hey, who was rece appointed to the chair of chemistry, King's Coll University of London.

Erratum.—In the communication by Prof. S Kravkov and L. P. Galotchkina entitled "Electrot in Colour Vision" published in *Nature* of May 1945 (p. 605), the current used was 0·02 mA., not 0·2 mA. as stated in the penultimate line of first column.

Need for Development of Tropical Ecological Studies

THE development of the Colonies in respect of their plant resources should be at the present a matter of considerable importance, and anything which may hinder that development equally a matter of concern. As a result of numerous discussions between ourselves, and in the light of our varied experiences and contacts, we believe that a widening and broadening of tropical ecology is essential, especially in so far as it affects the workers in the field and the teachers in British universities. We have all come to the conclusion that our previous ideas or knowledge of tropical ecology gained from British universities were faulty in one or more important particulars. These misconceptions can be ascribed in part to a lack of balance in the academic teaching.

To quote an example: it is not sufficiently appreciated that tropical rain forest does not cover the greater part of the area of the tropics, and insufficient attention is given to the wide distribution of fresh-water swamp forest, desert and deciduous or semi-deciduous forests. Again, the part played by man—the devastating effects of shifting cultivation, grazing and burning, resulting in large areas of savannah and grassland, which in most areas must be regarded as biotic climaxes—does not receive the consideration that it merits. These observations are commonplace to workers with practical experience of the tropical areas, but their neglect affords evidence of a faulty emphasis in academic teaching which requires further consideration.

It is also fair to say that in many of the Colonies insufficient importance is attached to the study of ecology and its practical application to forestry. A proper understanding of ecological methods is imperative for the development of tropical forestry; this is clearly evident from mistakes that have been made in the past, especially in the adoption of extensive and costly planting schemes. A sound ecological knowledge is an essential prerequisite of any scheme for the improvement of wild forests by methods involving natural regeneration.

The faulty emphasis in academic teaching is no doubt due to the fact that ecologists from Europe have very often confined their attention to a study of rain forests, and as a result the published accounts represent an atypical sample of the natural vegetation. Another factor is the somewhat restricted circulation of papers written by forestry officers, because the main emphasis is laid upon timber and crop production. An ecologist has only to glance at the working plans and maps of a forest-working circle in order to realize at once the wealth of valuable ecological information that they contain, and which, if they had a wider circulation, would materially alter our ideas of tropical ecology. Forest and botanist officers are usually so occupied with routine matters that they have not the time to publish the conclusions and theories that result from their long experience and from departmental information.

An impasse has more or less arisen which will have to be broken. Newcomers to forestry departments are loath to write papers because so much of the ground work has been done for them and is available departmentally, and anything they write can only contain a modicum of new research. It is therefore imperative that heads of forest departments in the Colonies should specifically direct one or more officers to study the available information and write up descriptions of the various types of vegetation and any ecological conclusions that emerge*. Only in this way can the balance in academic teaching be readjusted. In this connexion a very strong case exists for the appointment, at a suitable rate of pay, of trained specialists, for example, ecologist, pathologist, to each forest department. The training of future recruits depends on publications, and forest officers have to decide whether they will not be contributing more to the general good by publishing such results as they have, or by leaving their results in the department because they feel that professionally they are not quite complete. It is appreciated that in the tropics the magnitude of the problems, the immensity of the areas and the infinity of the species make the worker cautious in publishing anything. This outlook is markedly absent among those of us who have been trained in areas of relatively puny communities with but few species.

There is also the fact that colonial journals of forestry and agriculture do not have a wide enough circulation at home. It is clear that for these various reasons a great deal of available information is not placed within the reach of those who need it. A great step forward in remedying this defect could be made by increasing the circulation of the journals and by directing officers to write up co-ordinated accounts of the vegetation in their districts. At the same time, teachers in Britain should realize that much information is available, and that if they are prepared to write to the departments in the various Colonies this information will be placed at their disposal.

A further means of redressing the present one-sided outlook would be for forest departments to arrange an exchange system, so that their older and more experienced workers returned to teach for a year at the universities while the academic worker came out to the Colony and studied with the field workers. A sound case can also be made for the appointment of specialist officers to groups of closely situated Colonies. Not infrequently officers in different Colonies and countries are ignorant of work carried out in other places, and specialists would not only be of great value to the departments, but they would also be in a strategic position to write balanced and co-ordinated accounts which would be of inestimable value to future recruits.

A further point which must be noted is the fact that the British Isles form a difficult ground for training ecologists who are going out to the tropics. The area is small and extensively modified by man, and it is very poor in species. On account of this, synecology is very largely being replaced by autecology, or the study of the species. The forester in the tropics is engaged in studying and employing his knowledge of the reaction of certain preferred species against a background of the economics of the community, so that to him community studies are of paramount importance. New methods of teaching ecology must be introduced if persons trained in the United Kingdom are to make the best use of their knowledge when they go to tropical regions. Thus the description of tropical forests in terms of detailed floristics or quadrats is of very little value. There is very strong ground, therefore, to put forward a plea for greater emphasis in research and teaching on biological spectra, internal climate, root distribution, biota, water relations, soil types, etc., as characters determining the aspect and form of any community. Students should be trained to make ecological comparisons without the necessity of producing detailed systematic lists. When the ecologist or forester arrives in the tropics he will find that one or other department has a trained systematist who can prepare any list he desires. Only with teaching of this type may methods used in one area be applied with confidence to other areas that are specifically different, but with similar features determining the physiognomy of the vegetation. A further contribution could also be made by the establishment in the tropics of research stations, including a central tropical ecological bureau, for research and teaching in all aspects of tropical botany and zoology. The ecological bureau would best be sited in India where co-ordination of the work of other research stations could be carried out and articles published from time to time. This has been advocated before, and it is to be hoped that some move will be made in the near future. Such places have unrivalled opportunities for making use of the knowledge of local officers who could not be spared for a year in the British Isles.

---

* Champion's "Forest Types in India and Burma" is an admirabl model of what is needed.

In conclusion, it is hoped that these thoughts will be of value at a time when many Colonies will be restarting their departments and when, for some years to come, a big inflow of recruits will be necessary due to vacancies caused by the War. The gist of this communication may be summarized as follows: the somewhat lop-sided treatment of tropical ecology in British universities needs adjustment and more emphasis should be laid on non-floristic aspects. Forest departments in the Colonies should be prepared to publish their results, and their journals should have a wider circulation. Specialists should be appointed to forest departments of colonies or groups of colonies, and there should be an exchange arrangement of field officers with university teachers. Lastly, it is imperative that some more tropical research stations be established in the Colonies.

Mass Departure of Locust Swarms in Relation to Temperature

Flying swarms of locusts often cannot be effectively attacked from the air because of the danger to the aircraft. Attention is therefore focused on the circumstances in which a swarm will remain on the ground. In Kenya the desert locust, *Schistocerca gregaria* (Forsk.), roosts overnight in trees and shrubs and usually takes to flight at some time during the morning. The prediction of the time of take-off is important in deciding the number of sorties an aircraft can make before the locusts leave, and therefore the number of aircraft required and the distance from which they can usefully operate.

We have followed a nearly mature swarm (changing to yellow) from near Sotik (lat. 00° 40′ S., long. 35° 11′ E.) to the laying ground near Kaputir (lat. 02° 00′ N., long. 35° 27′ E.), and we were able to study its behaviour on the ground on ten out of seventeen days during April 25–May 11, 1945. Results from two pink (immature) swarms studied on March 23 and on April 4 are also included below. On each morning continuous observations were made of the various meteorological conditions and of the behaviour of the locusts. By means of a thermocouple inside a hypodermic needle, which was inserted right along the abdomen into the thorax, about seventy observations of body temperature were taken per hour.

It is well known that in the early morning locusts bask in the sun, turning the body so that the largest area is exposed normally to the sun's rays. This behaviour leads to the body temperature rising far above air temperature, and we have many records of body temperatures 10–17° C. warmer than the air. At any one moment, locusts from different microclimates often have widely different body temperatures (for example, 22·5° and 37·2° C.). The time at which the locusts stream away in concerted fashion is fairly sharply defined and can be observed within five minutes; before this, many locusts have been flying about for some time, but now great masses of them take off together.

There is little constancy about the body temperature at mass departure, but the air temperature (meteorological screen and also sling hygrometer) varied only between 19·0° and 23·0° C. The following table shows the air temperature at the time of mass departure, and the upper and lower limits of body temperature just before that time. The first two sets of figures refer to the two pink swarms.

Air	Body	Air	Body	Air	Body
23·0° C.	34·8–38·0° C.	19·5° C.	26·5–36·0° C.	21·0° C.	24·8–38·3° C.
20·9	31·0–38·0	20·0	22·0–28·4	21·0	27·5–34·5
20·5	25·7–28·0	20·2	22·1–34·6	19·0	26·0–31·5
19·7	21·0–32·5	22·2	22·5–37·2	20·2	22·4–27·0

It is thus not possible to select a narrow range of body temperatures at which mass departure occurs. Such a range would have to include 27·0° C. (the highest body temperature for the coolest swarm) and 34·8° C. (the lowest for the warmest swarm). Actually, it is improbable that the initiation of mass departure is due to the warmest animals in a cool swarm and the coolest in a hot one, so that the range of representative body temperatures at this time is probably greater than 8° C. By contrast, the air temperature varied only by 4° C.

Locusts will not fly if the body temperature is too low. It appears that mass departure is not due, however, to a *metabolic* effect of the body temperature, once that is high enough, but is a *reaction* to air temperature. It is well known that it is inaccurate to speak of *the* body temperature of a locust, for the abdomen is often much cooler and nearer air temperature than the thorax. Presumably, the antennæ and legs will have a temperature approximating fairly closely to that of the air, so there is no sensory difficulty in postulating such a reaction. Air temperature, too, is not uniform when the locusts leave; there is often a gradient from the hot ground to the cooler upper air.

The important point is that mass departure appears to be correlated with air temperature, so that other factors affecting it can be studied with a sling or Assmann hygrometer, and the expensive apparatus and skill required for taking body temperatures are not necessary. Further data could therefore be accumulated fairly quickly and easily by workers on different species under widely varying conditions.

Some further observations made in Kenya this season on an immature swarm in conditions of higher air humidity confirm the general conclusion reached above, but put the air temperature of mass departure at between 17° and 19° C. There is also evidence that the settling of a swarm in the evening is correlated quite closely with air temperature.

This work is part of a programme of research under the Anti-Locust Research Centre and is sponsored by the Inter-Departmental Committee for Locust Control.

Detection of Birds by Radar

In view of Lack and Varley's recent letter on this subject[1], it may be of interest to quote some passages from a German document prepared this year. Under the heading "Spurious Echoes" (*Scheinziele*), it is stated that "under special weather conditions up to 120 spurious echoes may be observed in an hour. Spurious targets occur especially near the mouths of rivers. Water temperatures which are higher than the temperature of the air seem to favour their appearance. There seems to be a definite connexion between wind direction and the direction of movement of the spurious echoes. Velocities up to 600 km./hr. The ratio of amplitudes between horizontal and vertical polarization is 3 : 1."

Apart from the figure for the velocity, all the facts given suggest that the spurious echoes are due to birds. I suggest that 600 km./hr. is either a misprint for 60, or else has arisen because one or two aircraft echoes have erroneously been reported among the *Scheinziele*. If the Germans really had observed false echoes travelling at such high speeds, we should surely have found them on our own very similar sets as well.

That birds are the cause of spurious echoes does not seem to have occurred to the Germans, for the document goes on: "The physical origin of spurious echoes is so far unexplained. It is probably a matter of sharply bounded layers of discontinuity in the atmosphere. Charges, cloud movements, aerial vortices, as well as the boundary region between two layers of air can be suggested as possibilities." It is then stated that such discontinuities have not been located hitherto, but that this may be due to the crudeness of the methods employed for the exploration of the atmosphere. A programme of research was, therefore, to be initiated on Heligoland, with the object of finding discontinuities only half a metre thick!

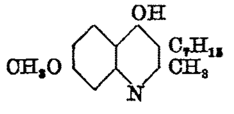
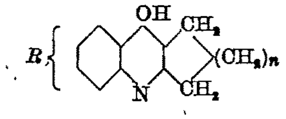
Antimalarial Activity in Tetrahydroacridones and Related Substances

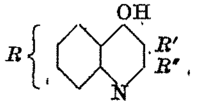
Fitch[1] has revealed the discovery by German workers of prophylactic activity in 4-hydroxy-7-methoxy-3-*n*-heptylquinaldine (I) against avian malaria. We have examined a number of tetrahydroacridones (II; $n = 2$), hydroxydihydro-β-quinindenes (II; $n = 1$) and 4-hydroxyquinolines for prophylactic activity in *P. gallinaceum* infections in chicks and have found noteworthy activity in certain compounds which, so far as the work has proceeded, conform to type (III), of which (I) and (II) are representative, R' and R'' being saturated hydrocarbon residues.



(I)



(II)



(III)

For example, 7-methoxyacridone shows no activity whereas its 1 : 2 : 3 : 4-tetrahydro derivative has a marked action.

The substances were prepared by the Conrad–Limpach reaction from the appropriate β-arylamino-αβ-unsaturated esters. A device which we have used for several years consists of effecting the cyclization in vigorously boiling diphenyl (b.p. 255°) instead of in liquid paraffin[2] heated to 260°; by this means the decomposition frequently accompanying this reaction is avoided and clean products are obtained in excellent yield.

A full account of this work will be published elsewhere at a later date.

A New Antimalarial Drug

Through the courtesy of Dr. J. Needham of the British Scientific Office in Chungking, samples of two indigenous plants regarded locally as of value in the treatment of malaria have been obtained and tested in experimental animals.

One of these, *Fraxinus malacophylla*, was found to be without action on *Plasmodium gallinaceum* in chicks. Contrary to the report of Liu *et al.*[1], no alkaloid could be found in the bark.

The root of a second plant, known locally as 'chang shan' and reputed to be *Dichroa febrifuga*, Lour., was ground and extracted with water and with dilute acid. Neither extract at a concentration where 1 c.c. corresponded to 1 gm. dry root gave the usual alkaloidal reactions, but both showed considerable activity against a trophozoite-induced infection of *P. gallinaceum* in chicks. The growth of exo-erythrocitic forms was not prevented by the extract.

Effect of some Arylcarbamic Esters and Related Compounds upon Cereals and other Plant Species

In the studies of the control of plant-growth by chemical compounds at Jealott's Hill Research Station, attention has been given to those compounds which affect cell extension growth (plant-growth substances), and to those which interfere with cell division. An earlier communication[1] has described work on plant-growth substances as selective weed-killers. The present letter describes our work on compounds which affect cell division.

Colchicine, acenaphthene, chloral hydrate and ethyl phenyl carbamate, all well known for their effects on cell division, were tested upon cereals. Lefevre[2] has described the morphological and cytological changes in plants caused by ethyl phenyl carbamate. We found that ethyl phenyl carbamate arrested the growth of cereals at lower concentrations than did colchicine, acenaphthene and chloral hydrate.

In December 1940 a differential effect was discovered. Ethyl phenyl carbamate, applied at 50 mgm. per sq. ft. to oats sown with charlock, affected the oats but not the charlock. The oats germinated and the first leaf appeared through the soil; then, however, growth was arrested; the first leaf ceased to grow in length, but its base became very much thickened and bulbous and no further leaves appeared. Root-growth ceased, and after remaining in this static condition for some time the seedling withered and died. Under certain conditions, applications as low as 10 mgm. per sq. ft. gave this effect. We found that 10 p.p.m. ethyl phenyl carbamate in aqueous solution in contact with the germinating cereal seed brought about this morphological effect. Higher concentrations prevented germination.

The activity of about fifty related arylcarbamic esters and thiocarbamates was then examined. Judged by the concentrations required to give the morphological effect, the relative activity of some of these compounds was as follows :

n-Butyl phenylcarbamate	active, but much less than ethyl phenylcarbamate.
Ethyl *o*-methoxyphenylcarbamate	
Methyl phenyl thiocarbamate	
Ethyl phenyl thiocarbamate	
n-Propyl phenylcarbamate	active, but less than ethyl phenylcarbamate.
Ethyl *o*-chlorophenylcarbamate	
Methyl phenylcarbamate	
Allyl phenylcarbamate	
N : N-Di(carboethoxyaniline) ..	activity equal to ethyl phenyl carbamate.
iso-Propyl phenylcarbamate ..	Activity approximately three times that of ethyl phenyl carbamate.

Aniline, α- and β-naphthylamine, methyl carbamate, urethane (ethyl carbamate) and formanilide were inactive under the conditions of our tests.

Iso-propyl phenylcarbamate in concentrations which stopped cereal seedling growth did not affect the growth of mangolds, sugar beet, flax, rape and yellow charlock. In heavier applications it arrested the growth of established cereal plants even when these were in flower, and, once arrested, very little or no further growth occurred. In one interesting experiment, 30–50 mgm. per square foot applied to winter rye during mid-May when the ears were just appearing resulted in fully formed heads containing no grain. The ears remained upright, whereas those of the untreated plants bent over under the weight of the grain.

This action of the aryl carbamic esters on monocotyledonous plants and lack of action on dicotyledonous is especially interesting, since it is the exact converse of the action we discovered with the growth substances of the phenoxy acetic acid class of plant-growth substances.

Fuller details of these and subsequent experiments are being published elsewhere.

Crystallization and Identity of the Triose and Triosephosphate Dehydrogenases of Muscle

The triose (glyceraldehyde) dehydrogenase was studied by Green, Needham and Dewan[1], who concluded from its distribution that it was a different enzyme from the triosephosphate dehydrogenase. We have succeeded in isolating and crystallizing the triose enzyme from rabbit skeletal muscle. After this was accomplished, we discovered that the crystals were in fact those of triosephosphate dehydrogenase. Their activity is actually some three hundred times greater with triosephosphate than with triose. It is therefore no longer necessary to assume the existence of triose dehydrogenase as a separate enzyme, as the two are identical.

The triosephosphate enzyme from yeast was crystallized by Warburg and Christian[2], who found that the pure enzyme also acted on glyceraldehyde, though only at about a thousandth of the rate with triosephosphate.

Our procedure for crystallizing the muscle enzyme is as follows : 600 gm. of muscle from a freshly killed and bled rabbit is cooled in ice, minced and extracted with 1,200 ml. of cold glass-distilled water. The extract is squeezed through muslin and about

0 per cent of the enzyme adsorbed on 240 ml. of calcium phosphate gel (33 mgm./ml. dry weight), sually in two stages. The gel is then extracted three times with 60 ml. of $M/15$ phosphate buffer pH 7·4, and the inactive extracts discarded. The enzyme is eluted with 100 ml. of the same buffer containing 10 per cent of ammonium sulphate. To the eluate 30 ml. of 5 per cent sodium pyrophosphate is added, and after cooling to 0° the enzyme is precipitated with 1·5 vol. of cold acetone (− 10°). The precipitate is centrifuged down, dissolved in 80 ml. f water and any insoluble part centrifuged off. The solution is now brought to 0·55 saturation with 28 gm. of ammonium sulphate and the precipitate filtered off. The filtrate is brought to 0·8 saturation with 4 gm. of ammonium sulphate. The precipitate, which contains the enzyme, is filtered off, dissolved in 40 ml. of water and 12·4 gm. of ammonium ulphate added. Any precipitate is filtered off and o the clear filtrate N caustic soda is added cautiously with stirring to bring the pH to 7·5. Crystals appear after 1–2 hours. They can readily be recrystallized by collecting them on a filter paper, dissolving in 20 ml. of water, adding 6·7 gm. of ammonium sulphate and bringing the pH to 7·5 again. Our preparations have been recrystallized three times.

The crystals were found to be quite free from zymohexase and lactic dehydrogenase.

A point of considerable interest is the large amount of the enzyme present in muscle extracts. From the activity of the crystals we calculate that the triosephosphate dehydrogenase actually forms about 10 per cent of the protein in the muscle extract.

The presence of a small amount of inorganic phosphate is necessary for the oxidation of glyceraldehyde or phosphoglyceraldehyde by the enzyme. (The same is true of the yeast enzyme[2].) This is interesting in view of the fact that the latter oxidation is coupled with phosphorylation but the former is not[3,4]. The reason for this difference is being studied. The activity of the enzyme is increased by cysteine or reduced glutathione and also by pyrophosphate.

After this work was carried out, we learned from the note of Cori, Slein and Cori[5], which only reached Britain during the past few days, that they have independently crystallized the triosephosphate dehydrogenase from rabbit muscle. Our crystals are evidently identical with those obtained by them. They too direct attention to the large amount of the enzyme present in muscle extracts, and they have actually obtained 7 per cent of the soluble protein as the crystalline enzyme. They also observed the activating effect of cysteine.

The properties of the pure enzyme are very similar to those of the albumin known as 'myogen B', crystallized from rabbit muscle extracts by Bailey[6] and Baranowski[7] independently. We think it is probable that they are one and the same protein.

Molecular Morphology of Myosin

RECENT investigations of the Szent-Györgyi school[1] have led to much new information about myosin and its role in muscular contraction. One of the main results is that myosin can be extracted from muscle in two forms: myosin *s.str.* and actomyosin. From both proteins threads can be drawn; those of actomyosin show a considerable contraction upon addition of adenosinetriphosphate. In solution, both forms are distinguished by the much higher viscosity of actomyosin.

In order to estimate the dimensions of the particles of both kinds of myosin, I undertook a study of the viscosity and anisotropy of flow of solutions of these substances. The viscosity of myosin is, in not too high concentration, independent on the velocity gradient in the viscometer. Actomyosin is much more viscous and the viscosity is strongly dependent upon the shear.

The study of the flow birefringence likewise revealed striking differences between the two myosins. In the case of myosin *s.str.*, the angle of isocline approaches a value of 78°[2], while actomyosin shows complete orientation at very low velocity gradients. Moreover, in the latter case, the intensity of the anisotropy of flow is much higher. While the difference in viscosity suggests a much more anisometric shape for the actomyosin particles, the observations on the double refraction of flow show that they are much longer than the myosin particles. Finally, the study of the light scattering of the solutions showed that the diameter of both kinds of particles is probably the same.

The results were evaluated quantitatively with the aid of the hydrodynamic derivations of J. M. Burgers for the motion of anisometric particles in a streaming fluid[3], assuming that both myosin and actomyosin particles have a cylindrical shape. It was found that the myosin particles are 10,000–11,000 A. long and the ratio of length to diameter is 162; their diameter is therefore about 65 A. This is in agreement with the electron micrographic observations, which show threads of about 60 A. diameter[4], while the X-ray diagrams of myosin threads reveal a periodicity of 66 A. perpendicular to the fibre axis[5]. The particles of actomyosin have a length-diameter ratio of about 2,000 and a probable length of about 13 µ.

Addition of adenosine triphosphate to a solution of actomyosin lowers the viscosity and flow birefringence to the values found with myosin. While this could be explained as due to the contraction of the particles, consideration of the changes in light scattering suggest that it is due to disaggregation, and that actomyosin is an aggregated myosin in which the aggregation takes place solely in a longitudinal direction. Urea in a concentration of 5 per cent also causes disaggregation.

The quantitative study of the effect of adenosine triphosphate on several physical properties of myosin and actomyosin showed that myosin reacts with it in units of particle-weight 100,000. The same value is found for the molecular weight of myosin in 45 per cent urea[6]. These particles seem to be the units of the myosin molecule. Myosin and adenosine triphosphate form an undissociated compound in stoichiometrical relation. After being bound to the myosin, the adenosine triphosphate is split. This reaction is not inhibited by adenylic acid and phosphoric acid, as the splitting takes place only so far as adenosine diphosphate.

The investigation of the viscosity of myosin in 45 per cent urea showed that the units in question are single peptide chains with a length of 2,000 A. In the longitudinal direction of a myosin particle, five such chains are placed end to end, while in cross-section the particle has about 50 chains. It is striking that the total length of a particle (1 μ) is exactly identical with the length of the anisotropic disks of the muscle fibril.

Heat Coagulation of Muscle Proteins

A CHANGE in pH when proteins are denatured has been reported by other workers[1,2]. When making observations of the change in pH of meat resulting from heat coagulation, we were struck both by the magnitude and by the variability of the change. Muscle is a highly buffered system[3], and a change such as that observed, for example, from 5·6 to 5·9, indicates the production of a considerable amount of base.

The magnitude of a change in pH in a buffered system is of itself of little significance; what is important to know is the actual equivalent of base produced per unit weight of coagulated protein. We have therefore carried out experiments with muscle press-juice to determine this quantity, varying both the initial pH and the concentration of coagulable protein in the system.

The juice was obtained by grinding minced lean beef with washed quartz sand, and pressing through calico. Coagulable protein was determined by precipitation with trichloroacetic acid and determination of nitrogen in the precipitate. Results are expressed in terms of nitrogen. A series of dilutions of the juice was prepared. After measurement of initial pH with the glass electrode, the proteins were coagulated by immersion in boiling water, the coagulum cooled to 20° C., and the pH determined. The buffering power ($\delta B/\delta p\text{H}$) of the system in the range of pH covered by the observed change (ΔpH) was determined by titration, after coagulation, with 0·05 N hydrochloric acid. This enabled the increment in basic equivalents (ΔB) to be calculated.

The specimen data in Table 1 illustrate the effect of diluting the juice on the magnitude of ΔB. The first group relate to a sample of fresh meat, the second to frozen meat after several years in stor. In each case the initial pH was 5·5.

TABLE 1.

Coagulable N (%)	ΔpH	ΔB (milliequiv.) per gm. coagulable N.
1·05	0·22	0·94
0·525	0·21	0·76
0·263	0·18	$0{\cdot}57_5$
1·32	0·22	0·73
0·66	0·23	0·60
0·33	0·19	0·47
0·165	0·16	0·35

The value of expressing the results in terms of Δ rather than of ΔpH is evident when the figures i the last two columns are compared. Buffering pow changes considerably both with dilution and pH, is seen in Table 2. In the range studied, most of th variation of $\delta B/\delta p$H with pH is due to the phosphat present in the juice.

These experiments have been repeated with d alysed juice, in which the buffering is due to th protein alone, and values of ΔB of the same ord have been obtained, although ΔpH is, of cours much higher.

These results show that at any given pH, th production of basic groups is not, as one might hav expected, proportional to the amount of protei undergoing coagulation; ΔB per gm. of coagulabl nitrogen decreases with increasing dilution. If Δ per gm. of coagulable nitrogen is plotted agains the log of the coagulable nitrogen concentration, straight line is obtained. This effect is not due t incomplete coagulation, or to a shift in the curv relating ΔpH to pH, since it occurs at all pH value studied. Qualitatively, there seemed to be som correlation between the size of the aggregates forme and the concentration of protein, the larger aggregates being produced in the more concentrate systems, that is, those in which ΔB per gm. o coagulable nitrogen is greatest. This would sugges that the liberation of base might occur as a result o aggregation rather than of the denaturation whic precedes aggregation.

The effect of varying initial pH at constant concentration of protein is shown in Table 2. Th coagulable nitrogen in the press-juice in this instanc was 0·525 per cent.

TABLE 2.

Initial pH	Final pH	ΔpH	δB (milliequiv. per 100 c.c juice) / δpH	ΔB (milliequiv.) per gm. coagulable N
4·50	4·72	0·22	2·48	1·04
4·98	5·20	0·22	2·17	0·91
5·47	5·68	0·21	1·90	0·76
5·96	$6{\cdot}06_5$	$0{\cdot}10_5$	1·87	$0{\cdot}37_5$
6·02	6·13	0·11	1·97	0·41
6·46	6·46	0·00	2·82	0·00
6·70	6·65	−0·05	2·88	$-0{\cdot}22_5$
7·72	7·45	−0·18	1·64	−0·56

The change in sign of ΔpH and ΔB occurred, i this and other samples, at a point slightly on th acid side of neutrality. The predominating protei fraction in muscle juice is myogen, which has it isoelectric point at 6·5–6·7[4], and in following u the theoretical implications of these observations th fact deserves bearing in mind. It must also b remembered, however, that Pauli and Koelbl[5] foun this 'inversion point' to be in the neighbourhood o pH 8·4 in the case of egg albumin and serum albumin which is well on the alkaline side of the isoelectri point of these proteins.

The change in pH probably arises from at leas two distinct causes. Association of protein molecule into aggregates large enough to possess an effectiv internal phase at any pH other than the isoelectri point is likely to cause a change in the total charg on the protein component of the system, and therefore a change in pH of the aqueous medium in whic it is dispersed; and denaturation, whether accompanied by aggregation or not, in so far as it involve interaction between acidic and basic groups on th protein, must likewise affect the pH of the medium hese possibilities are being investigated by following e titration curves of the native and denatured pro-in and the changes in amino-nitrogen accompanying enaturation and coagulation.

This work was carried out as part of the programme f the Food Investigation Board, and is published by ermission of the Department of Scientific and ndustrial Research.

Activity of Helvolic Acid against *Mycobacterium tuberculosis*

THE earliest account of an action by *Aspergillus umigatus* on the tubercle bacillus appears to be hat of Vaudremer, who found that *Myco. tuberculosis* ncubated for 24 days in a filtered extract of *A. umigatus* lost to a large extent its acid-fast staining roperties and its virulence for animals, as compared with bacilli incubated in Raulin's culture fluid or in aline[1]. The active principle was thermostable[2]. He sed similar extracts to treat more than two hundred atients with tuberculosis, but clinical results were quivocal[3]. He also pursued the idea of using the ttenuated bacilli for the preparation of vaccines[4,5].

Zorzoli[6] found that medium on which *A. fumigatus* ad grown interfered with the growth of *Myco. uberculosis*; the active substance withstood 100° C. or one hour. Soltys[7] similarly found that medium rom this mould inhibited the growth of human, ovine and avian *Myco. tuberculosis* and *Myco. phlei*, nd that it had the same heat stability. By partial urification Asheshov and Strelitz[8] obtained an xtract from culture filtrates which killed B.C.G. at 1 in 500,000 and inhibited its growth at 1 in 1,400,000 nder the conditions of their experiments, though avian *Myco. tuberculosis* was not killed by a concentration ven as strong as 1 per cent. Kallós[9] and Gerber and ross[10] each reported that culture filtrate from an nidentified strain of *Aspergillus* contained a substance active against *Myco. tuberculosis*, and Miller nd Rekate[11] found an unidentified mould of which he mycelium inhibited its growth.

There is little information from the chemical evidence presented in these reports as to how far the activity of crude extracts against the tubercle bacillus might be accounted for by any of the antibiotic substances already isolated from the metabolic products of *A. fumigatus*. It may therefore be of interest to workers in this field to report the activity, under a given set of experimental conditions, of helvolic acid[12,13], the only one of these antibiotics which approaches the status of a chemotherapeutic agent. Mr. T. I. Williams, who had been working with helvolic acid, suggested making these observations.

Human *Myco. tuberculosis* in sputum was cultured by Muller's[14] adaptation of the slide culture technique[15], the medium being distilled water with 25 per cent packed human red blood cells from citrated blood, incorporating serial dilutions of helvolic acid (1 in 1,000, 10,000 and 100,000). The activity of the elvolic acid did not deteriorate during the incubation eriod of one week. When at this time the preparations were fixed and stained, some colonies, though fewer and smaller than in the controls, had developed in the presence of 1 in 100,000 helvolic acid, but the higher concentrations, 1 in 10,000 and 1 in 1,000, had suppressed multiplication completely.

Thus under these conditions of experiment, helvolic acid inhibits the growth of the tubercle bacillus partially at a dilution of 1 in 100,000 and completely at at least 1 in 10,000.

A Polysaccharide from *Gigartina stellata*: the Isolation of Crystalline 2:6-Dimethyl-β-*d*-Galactopyranose from the Methylated Polysaccharide

THROUGH the kindness of Dr. A. P. Orr of the Marine Station, Millport, in supplying a quantity of *Gigartina stellata* which is used in the preparation of 'British Agar'[1], we have been able to investigate a polysaccharide isolated from this material.

After washing for a week in running water, the seaweed was extracted with hot water, the extract concentrated under diminished pressure and the hot extract precipitated with alcohol. The product is essentially a polysaccharide ethereal sulphate of $[\alpha]_D^{15°}$ + 51° in water, ash 17·5 per cent (as sulphate) giving Ca, 3·7; Mg, 1·0; SO_4, 12·7 per cent calculated on the weight of hot extract, whereas the total sulphate was 23·8 per cent.

Hydrolysis of the hot extract with $N/2$ oxalic acid followed by neutralization with barium carbonate gave *d*-galactose (40 per cent) together with the barium salt of an acid (30 per cent), the constitution of which has not yet been decided.

As with the polysaccharide ethereal sulphates of *Chondrus crispus*[2], which is also used in the preparation of 'British Agar', direct methylation of the hot extract was slow, but it could be acetylated readily in the cold after a preliminary treatment with pyridine[3]. Simultaneous deacetylation and methylation yielded a partly methylated product, the methoxyl content of which was raised by several similar treatments to *c.* 20 per cent. The methylated polysaccharide so obtained closely resembled the original hot extract $[\alpha]_D^{15°}$ + 43° in water, ash 18·2 per cent (as sulphate) giving Ca, 3·8; Mg, 0·9; SO_4, 12·8 per cent (calculated on the weight of the methylated hot extract); total sulphate 24·7 per cent.

Hydrolysis of this methylated polysaccharide and suitable treatment gave as the main product a dimethyl methylgalactoside (b.p. 145–155°/0·10 mm., $n_D^{10°}$ 1·4737) from which on methylation, hydrolysis and treatment with aniline a good yield of tetramethyl-*d*-galactopyranose anilide was obtained, thus indicating the absence of substitution on C_5. The dimethyl methylgalactoside ditoluene-*p*-sulphonate underwent no reaction with sodium iodide in acetone[4], indicating the presence of a methoxyl group on C_6. Removal of the glycosidic methoxyl gave a crystalline dimethyl galactose (m.p. 119–120°, $[\alpha]_D^{15°} + 48°$ (10 min.) $\rightarrow + 87{\cdot}1°$ (240 min. in water; constant)). This sugar on osazone formation gave pure 6-methyl galactosazone, proving substitution on C_2 and C_6. Further confirmation that this sugar is identical with the 2 : 6-dimethyl-β-*d*-galactose synthesized by Oldham and Bell[5] was obtained as follows. Oxidation gave a crystalline acid which, on distillation at 180°/0·02 mm., yielded a dimethyl galactonolactone $[\alpha]_D^{17°} - 49° \rightarrow - 24°$ (28 days in water, still incomplete), the negative rotation and slow hydrolysis proving it to be a γ-lactone. The dimethyl galactose on glycoside formation at room temperature gave a mixture of dimethyl galactofuranosides as shown by the negative rotation, $[\alpha]_D^{13°} - 43°$ in methanolic hydrogen chloride (1 per cent). These facts prove C_4 to be unsubstituted. The syrupy lactone gave an amide, m.p. 154–155°, $[\alpha]_D^{16°} + 46°$ in water, which gave a negative Weerman reaction, confirming the evidence from the osazone that a methoxyl residue is present on C_2.

The dimethyl galactose gave a crystalline anilide, m.p. 121–122°, $[\alpha]_D^{17°} + 15°$ in ethanol, which is clearly not identical with the 2 : 3-dimethyl galactose anilide, m.p. 130–131°, $[\alpha]_D^{15°} + 119°$ in ethanol of Robertson and Lamb[6]; the anilide is not particularly suitable as a derivative for characterizing this sugar since it is difficult to purify.

The dimethyl-γ-galactonolactone was converted into the phenylhydrazide, m.p. 140°, not depressed on admixture with a synthetic specimen which we received recently from Dr. D. J. Bell, and the crystalline dimethyl sugar suffered no depression of melting point on admixture with an authentic specimen supplied by him. Furthermore, we have prepared a crystalline dimethyl-β-methyl-galactoside, m.p. 72° $[\alpha]_D^{19°} - 22°$ in chloroform, and its 2 : 3-monoacetone derivative, m.p. 54°, the properties of which are in good agreement with those recorded by Dr. Bell[7] in his recent studies on synthetic dimethyl galactose. No doubt remains, therefore, that this dimethyl galactose isolated in crystalline form from a natural source for the first time is, in fact, 2 : 6-dimethyl-β-*d*-galactopyranose.

Since the rate of removal of sulphate from the hot extract with *N* sodium hydroxide at 100° is exceedingly slow (62 per cent in 3 days), it is concluded that the sulphate group is located on C_4[2,8] and that the galactopyranose residues are linked to adjacent units through C_1 and C_3. The absence of α-glycol groups is confirmed by the failure of the polysaccharide to react with periodic acid. It may be recalled that a similar structure for the galactose residues was proposed for the corresponding polysaccharide[2,8] isolated from *Chondrus crispus*, although in this instance owing to the difficulty of methylation no crystalline 2 : 6-dimethyl galactose was isolated.

No definite pronouncement can be made as yet about the non-galactosic moiety, but certain of its properties are not inconsistent with those of a keto hexonic acid; it may be recalled that 2-ketogluconic acid has been isolated recently from Irish moss by Young and Rice[9]. Further work is in progress on this question.

Resistivity of Thin Metallic Films

IN continuation of work carried out in this Laboratory on the electric and magnetic properties of thin metallic films[1], we have now investigated the resistivity of nickel films (20 mμ–700 mμ) between − 236° C. and 400° C. The films are deposited on thin glass sheets by using cathodic sputtering in an atmosphere of hydrogen gas, carefully purified. We measured the electric resistance as a function of thickness and temperature below and above the Curie point. Between 0° C. and − 183° C., we found approximately a linear variation of the resistance with temperature. Below − 183° C. and also between 0° C. and the Curie point this is not the case. Above 358° C. the temperature coefficient of the resistance is again constant.

Like Colombiani[2], we found that below a certain thickness (for our films 40 mμ, while he finds as limit 220 mμ) the nickel films possess a negative temperature coefficient. This limit seems not to be greatly changed by sintering. Fig. 1 shows the average temperature coefficient, α, corresponding to the temperature region − 78° C. and 0° C. as a function of thickness.

We investigated specially the variation of the resistance in the neighbourhood of the Curie point. In Fig. 2, $(1/R_0)\,(dR/dT)$ is shown as a function of temperature. The curve for normal nickel has been computed from measurements made by Gerlach and

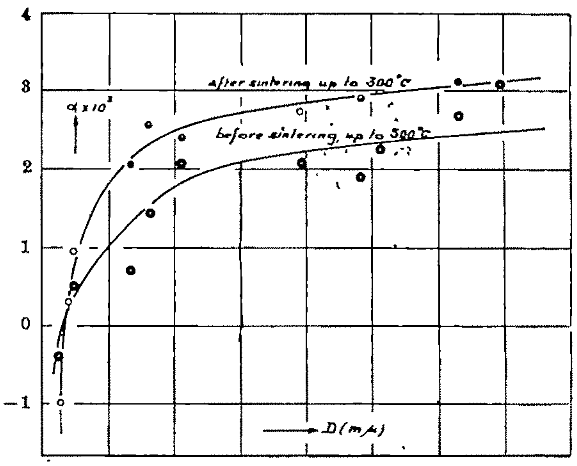

Fig. 1.

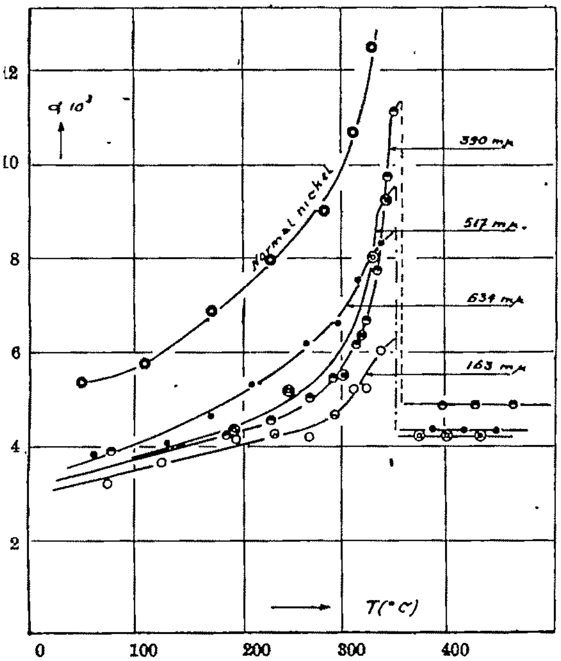

Fig. 2.

Schneiderhan[3]. The form of the curves obtained seems very difficult to interpret because two effects are concerned, namely, the dependency of the spontaneous magnetization on thickness, and secondly the behaviour of thin films as semiconductors.

Performance of Diffusion Pumps

REPORTING recently on the vacuums produced by diffusion pumps, Ray and Sengupta[1] quote my statement "that the limit of pumping is set at the vapour pressure of the pump fluid at room temperature" and then proceed to take gentle issue with me. The correctness of my statement and of their counter-findings are, surely, both a matter of definition.

When the modern, rotary, oil-immersed mechanical pump was introduced, it was usual to place a charcoal or liquid-air trap in the vacuum circuit to obtain low pressures. Similarly the Gaede–Langmuir vapour pump required a vapour trap for proper operation. It thus became the practice to express the ultimate performance of all kinds of high-vacuum pumps as though they would be used with a cooled trap. Langmuir's contention[2] that his mercury pump could attain an indefinitely high vacuum with liquid air was as valid as the equally prevalent belief that the vacuum without the trap would be limited to about 2×10^{-3} mμ, which is vapour pressure of mercury at room temperature.

The situation was satisfactory to all parties until C. R. Burch[3] invented the phlegmatic oil-filling to replace mercury in a condensation pump. Pressures of 10^{-6} mm. were immediately available *without* a cooled trap. To compare the performance of an oil-filled pump with a mercury pump under trapped conditions was manifestly wrong since the whole point of the oil pump was to dispense with the trap. Unfortunately, the manufacturers of oil-sealed mechanical pumps and mercury diffusion pumps found it desirable to continue describing performance in conjunction with a trap, even though mechanical pumps are now generally used without a trap. Thus a well-known laboratory mechanical pump is advertised to produce an ultimate vacuum of 10^{-4} mm. (there is no mention of a trap) though the limit as measured by a Pirani, ionization or Knudsen gauge applied directly to the pump is about 8 microns.

Those of us whose programme required fast economical pumps found the oil-filled diffusion pump to merit the most intensive study. It was soon apparent that the vacuum available was a little poorer (higher pressure) than the vapour pressure of the operating fluid at room temperature. The degradation of vacuum was due to volatile impurities and products of decomposition. To circumvent these the self-purifying pump was devised. Such a pump, used under optimum conditions of construction and type of fluid, provides a vacuum which is almost exactly equal to the vapour pressure[4] of the main constituent of the fluid at the temperature of the entrance to the pump (usually room temperature). When Ray and Sengupta make a distinction between the vapour pressure of the fluid and the partial pressure of residual air, they tacitly accept my definition and at the same time provide a method of calculating the ultimate vacuum that would be available with a strongly cooled trap.

There are, of course, conditions where my statement would not hold. The definition applies to vapours generated at relatively low boiler pressures and ejected at slow speed through wide openings. This condition has hitherto been necessary with organic fluids to avoid decomposition. The multi-stage steam ejector does not suffer from these limitations, and manufacturers have succeeded in producing, with four or five stages and appropriate inter-condensers, 'blank off' pressures of 5–10 microns, which are about 5,000 times lower than the vapour pressure of water at room temperature. This must mean that the steam issuing from the final jet has been accelerated uniformly to such a speed and so thoroughly robbed of random motion that not one water molecule in many millions is guilty of 'back-streaming'.

The evolution of the high-vacuum pump is likely to continue for many years, and it would be rash to speculate on an ultimate design. The very large pumps required to maintain vacuums in the 'wet' system of heavy chemical industry—the molecular distillation of natural oils, for example[5]—employ many operating stages and subsidiary equipment and warrant the term 'vacuum engine' rather than pump.

Type of pump	Optimum speed (litres/sec.)	Ultimate vacuum untrapped (mm. Hg)	Watts input	Ratio, watts per litre/sec.
Mercury, single-stage, early American	10	$2\cdot5 \times 10^{-3}$	1500	150
Mercury, single-stage, early German	25	$2\cdot5 \times 10^{-3}$	400	160
Mercury, three-stage, recent German	20	$2\cdot5 \times 10^{-3}$	1800	90
Oil, single-stage, recent British	125	10^{-6}	1350	10·8
Oil, single-stage, recent American	220	5×10^{-6}	220	1·0
Oil, three-stage fractionating, recent American	1200	6×10^{-6}	1000	0·8

Evidently a small increase of efficiency of jet, boiler or fluid may have cumulative effects of considerable moment in reducing operating costs. Some idea of the trends in performance may be gathered from the accompanying table compiled by my associate, Mr. F. M. Jenner, for pumps of laboratory size that have been introduced during the past twenty years.

Comparative Vacua Produced by Different Oils in a Diffusion Pump

In our previous communication[1] it was noted that the vapour pressure of the pump fluid affects the total vacuum only by a minor fraction, and the pump continues to exhaust air from the chamber to be evacuated to a pressure far below the vapour pressure of the fluid. A picture of the pumping action has also been suggested.

The practical independence of ultimate vacuum on a change of pump fluids has been studied in subsequent experiments[2]. Different types of fillings were used: Apiezon *B*, Capella *D* (Caltex), Mobile *B*, Petroleum jelly (white) and solid paraffin. They gave the same ultimate vacuum with a single-stage diffusion pump within the workable range of adjustments (see table). The increase of heat input with the petroleum jelly and solid paraffin fillings are worth mentioning. In these cases the flow of water had to be reduced in order to keep the body of the pump sufficiently warm.

The total pressure was measured by a Pirani gauge and the partial pressure by a McLeod gauge.

EFFECT OF PUMP FLUIDS ON THE PRODUCTION OF VACUUM BY A SINGLE-STAGE DIFFUSION PUMP (PRESSURE IN $\mu = 10^{-3}$ MM. MERCURY).

Pump filling	Vacuum conditions		Relative heat input (estimated)	Remarks
	Partial pressure of air	Partial pressure of fluid vapour*		
Apiezon oil	0·03	0·10	1	
Capella *D* (Caltex)	0·03	0·17	1·5	
Mobile *B*	0·03	0·97	1·5	
Petroleum jelly (white)	0·03	0·67	2	Water circulation is to be low enough to maintain fluidity and adequate boiling
Solid paraffin	0·03	0·57	2·5–3	,,

* This is, however, not the true vapour pressure of the fluid under static saturation condition, as the pressure is measured under constant pumping condition.

In another experiment solid paraffin was used in a three-compartment fractionating pump. The suction of air was not improved, but the back diffusion of fluid vapour was markedly reduced. With a single-stage pump it was 0·57 μ (see table), but with the three-compartment pump it came down to 0·06 μ. These experiments corroborate our picture of the working of a diffusion pump.

Our thanks are due to Prof. M. N. Saha for his interest in the work, and also to the authorities of the B.S.I.R. for a financial grant to carry out the investigation.

An Illusion of Size

In his letter, Mr. J. Phelps[1] refers to an interesting point in the manufacture of threepences, namely, their expansion in the coining press into dodecagonal steel collars. The fact that the corners of coins subsequent to 1940 are more rounded than are those of earlier ones seems to point to a change in the collars at about that date. If this is the case, it will also explain the change in the size of the coins which occurred at about the same time referred to in my letter[2].

The difference in size of the old and new issue is easily demonstrated with callipers, for if these are adjusted to be a tight fit on little-worn coins of the old issue they will be found to be quite loose on similar coins of the new one.

Mr. Phelps's statement that the edges of all coins become rounded in circulation is almost certainly correct, but I do not think that it accounts satisfactorily for the 'illusion', for the statement made by Dr. A. Loewenstein[3] was that it was the new coins which appeared to be the smaller, whereas according to Mr. Phelps it should be the old ones with worn edges which appear to be the smaller.

I feel that the word 'illusion' should not be used where actual differences of shape exist such as these. It should be reserved for cases where a faulty judgment has been made because of some defect in a sense-organ. All the familiar optical illusions come in this category.

When light is failing, and I am not wearing spectacles, I tend to confuse two-shilling pieces with half-crowns. This is an illusion which I find embarrassing. Would it be possible for one of these coins to be given the dodecagonal shape of the threepenny piece?

[2] *Nature*, 156, 118 (1945).

[3] *Nature*, 155, 672 (1945).

To see if Prof. H. Hartridge's explanation[1] of the effect discovered by Dr. A. Loewenstein[2] was justified, the experiment described by them was repeated on a comprehensive scale. Four nickel threepenny bits coined in 1942 were selected and two of them had their edges and heads filed off* so that a flat surface was obtained on both. One coin of each pair was

* Permission to mutilate the coins was obtained from the Deputy Master and Comptroller of the Royal Mint.

olished to a high degree: special attention was paid o the regions near the edges being as bright as those near the centre. The other filed coin was brought into contact with 'Plasticene', which tarnished its urface immediately. This was more satisfactory than oxidation by heating, since the risk of deforming the oin was eliminated. The remaining coin was dull and needed no attention.

The filed and normal coins were placed in pairs on the same neutral background and illuminated by a parallel beam of light from a carbon arc. Four ilters were used: Ilford Nos. 204, 304, 404 (red, lue, green) and one neutral-tinted plate. Nineteen observers were told that the respective pairs consisted of reputedly equal coins, and each put down his esult for eight observations: four each for perpendicular and oblique illumination. All observations were carried out *along* the reflected beam.

It is found that, in the case of oblique lighting, the bright coin appears to be the larger in all cases except for the filed coins illuminated by neutral light. This general result is to be expected on account of rradiation. The observations for perpendicular ncidence are much less convincing: in the case of the filed coins, the dull appeared to be the larger in all except blue light, and there the difference is too small to defy confirmation. It is to be expected that the scales would tip in favour of the dull coin, since another set of experiments to be published in detail elsewhere demonstrated the independence of the effect on the colour of the filter. Moreover, in the instances where the dull coin in general appeared to be the larger, the filed coin showed the effect in a much more pronounced way than the normal threepenny bit. This is rather remarkable since perpendicular illumination might be expected sensibly to diminish the appearance of unevenness of the normal coin, as all shadows are greatly reduced.

The fact that the filed coin is much more effective n giving the illusion of size indicates that an explanation of the phenomenon may have to be rejected f it is based on the way light is reflected from the coins. This applies not only to Prof. Hartridge's note but also to that of Mr. Phelps[3].

Measurement of Ultrasonic Velocities in Extended Solids

FOR extended solids, the ultrasonic frequencies to be used for any reasonable propagation of the waves through them must be low, say, 500 kilocycles and less, for the vibrations of higher frequencies will be excessively damped. For determination of velocities at higher frequencies, a method based on the Debye–Sears ultrasonic diffraction of light has already been indicated[1], and in the following we will describe the method found for the lower frequencies.

Two quartz crystals, T and R, X-cut and of equal thickness, were attached to the opposite ends of a 3 ft. column (3 in. × 3 in.) of cement-sand concrete. The ultrasonic vibrations (frequency 300 kc./sec.) were sent by T and received by R after their propagation in the solid. The voltage developed at R by piezo-electric action was fed to the input of a vacuum-tube ultrasonic detector specially made for the purpose (employing two stages of radio-frequency amplification followed by one of rectification and one of D.C. amplification), such that the presence of an input voltage at the grid of the first valve gave a change in the steady plate-current of the last valve. The vibrations at T were produced by a conventional Hartley-type transmitting circuit. The voltages tending to reach the input of the detector were of two origins, one of ultrasonic origin from R, and the other due to the electromagnetic waves coming from the transmitting circuit. By exposing the screened lead coming from the crystal R, or exposing the grid of the first valve under controlled conditions, it could be arranged that the voltage due to the electromagnetic waves was much greater than that of ultrasonic origin, but not so much as to prevent the possibility of the indication of the latter. The change in the plate-current of the last valve of the ultrasonic detector was due to the vector sum of the two voltages, and by varying the frequency of the transmitting circuit (tuning of the detector system being adjusted simultaneously) through a small region, say, 5,000 cycles or less, so that the change of frequency did not go beyond the resonance region of the crystals, a maximum and minimum of the plate-current could be produced. Evidently the maximum occurred when both voltages were in phase, and the minimum when they were in antiphase. Now the phase of the electromagnetic waves reaching the ultrasonic detector was only negligibly changed, if at all, in this small variation of frequency due to their long wave-length (1,000 metres) as compared to the distance between the transmitting circuit and the ultrasonic detector (a few feet). So, for the minimum of plate current the phase of the voltage of ultrasonic origin had changed sign. This indicated that the number of ultrasonic wave-lengths in the solid column had changed by half a wave-length.

Let f be the length of the column, f_1 and λ_1 the frequency and wave-length for maximum current, and f_2 and λ_2 for minimum current, and v the velocity of ultrasonics, assumed the same for both frequencies. Then

$$l = n\lambda_1 = (n \pm \tfrac{1}{2})\,\lambda_2$$

or

$$l = n\frac{v}{f_1} = (n \pm \tfrac{1}{2})\frac{v}{f_2}.$$

From which

$$v = 2l(f_1 \sim f_2).$$

Taking v as about 6,000 m./sec., l as 2 ft., $f_1 \sim f_2$ is about 5,000 cycles/sec., which can be easily measured by modern technique.

The region of resonance frequencies of the quartz can be easily made to contain this frequency interval, as was the case in our experiments. For lower frequencies, the thickness of the quartz is comparable to its other dimensions, and so by the coupling of the different resonance frequencies, the resonance frequency region is made sufficiently broad.

It is hoped to publish the full details of the apparatus and the quantitative results obtained in due course.

FRIEDEL-CRAFTS CATALYSTS AND POLYMERIZATION

A CONFERENCE on "Friedel-Crafts Catalysts and Polymèrisation" was held on Saturday, September 15, in the Chemistry Department of the University of Manchester. This Conference was convened by Prof. M. Polanyi, and some hundred and seventy academic and industrial research workers were present. In welcoming the guests, Prof. Polanyi said that similar meetings on a smaller scale had been held previously at the Universities of Manchester and Leeds, but that this was the first large-scale meeting of its kind, in which the subject under discussion was of such general interest to both academic and industrial research workers. He hoped that further conferences of a similar nature would be held.

The first part of the discussion was concerned with the physical chemistry of the Friedel-Crafts catalysts. Dr. F. Fairbrother, in a paper on "The Catalytic Halides", discussed the reasons for the catalytic activity of these halides, and the way in which their catalytic power is exercised. One of the outstanding features of these Friedel-Crafts catalysts is that they are all electrophilic in character, and Dr. Fairbrother described two kinds of experimental investigation by which a comparison of the electrophilic character of inorganic halides may be made. The first was the study of the exchange of radioactive bromine between an organic bromide and an inorganic bromide. From these experiments it was found that the ease of halogen exchange could be correlated with the catalytic activity of the inorganic bromide on one hand, and with the ionizability of the organic bromide on the other hand. This exchange of radio-bromine must mean that the interaction of the inorganic bromide with the organic bromide causes the original C—Br bond to break. This was discussed in terms of the reaction:

$$M\,\mathrm{Hal}_n + R\,\mathrm{Hal} \rightleftarrows (M\,\mathrm{Hal}_n \,.\, R\,\mathrm{Hal}) \rightleftarrows M\,\mathrm{Hal}^-_{n+1} + R^+.$$

That is, the exchange may take place through the formation of an ion pair, the partners of which are able to rotate relative to one another, so that on disengagement and reformation of neutral molecules an exchange of halogen atoms may have taken place. If a polar but un-ionized addition compound is formed, the actual exchange of bromine atoms, it was suggested, could only occur by the rupture of such an addition compound. In the second experimental investigation which Dr. Fairbrother described, dielectric polarization measurements were carried out on solutions containing a metallic bromide and an organic bromide to determine the equilibrium concentration of ion pairs. This equilibrium concentration was found to be very small in general, as had been predicted from a consideration of the endothermicity of the process. These findings were also confirmed by measurements of the dielectric polarization and colour of metal halide – triphenylmethyl halide double compounds.

Dr. H. A. Skinner spoke on "The Molecular Structures of the Catalytic Halides". He summarized the results of electron diffraction studies of the halides of Groups II, III, IV and V of the Periodic Table. These results showed that, in general, the metal – halogen bond distances are shorter than those which would be expected if the bonds were of the normal covalent type. For those metal halides known to show catalytic activity in Friedel-Crafts reaction the most active catalysts show a greater percenta bond-contraction than do the weaker catalysts. Th fact that the silicon halides are not catalyticall active although they show a marked bond co traction was considered in relation to the low dipo moment of the Si—Cl bond, and the suggestion w made that one of the factors upon which the catalyt activity of the halide $M-X$ depends is the ion nature of the bond in the sense $M^+ X^-$.

Thermochemical calculations were given for th interaction of the catalyst and the organic halid for the case of boron trifluoride and organic fluorid The three reactions

(a) $CH_3F + BF_3 \rightarrow CH_3^+ [BF_4]^-$
(b) $(CH_3)_3CF + BF_3 \rightarrow (CH_3)_3 C^+ [BF_4]^-$
(c) $(Ph)_3 CF + BF_3 \rightarrow Ph_3 C^+ [BF_4]^-$

were examined, and the conclusion was reached tha reaction (a) is endothermic and unlikely to occu whereas reactions (b) and (c) are exothermic, an probably will occur. These results were compare with the experimental observations of Burwell an Archer that the tertiary alkyl fluorides more readil undergo Friedel-Crafts reactions in the presence boron trifluoride than do the primary alkyl fluoride and with the fact observed by Wiberg, that tr phenylmethyl fluoride readily forms a complex wit boron trifluoride.

Dr. P. H. Sykes, in a paper on "Friedel-Craft Catalysts in Carbon-Monoxide Reactions", discusse the addition of carbon monoxide to ethers, alky halides, alcohols and aromatic hydrocarbons usin aluminium chloride, boron trifluoride, hydroge fluoride and sulphuric acid as catalysts. Dr. Syke discussed the formation of complexes between th catalyst and the reactants and between the catalys and the products, and suggested that in many case the effectiveness of the catalyst is due to the fac that the decrease in free energy from catalyst reactant complex to catalyst-product complex is mor marked than the decrease in free energy of th reaction in the absence of catalyst. It was suggeste that this is the reason why aluminium chlorid catalyses the production of benzaldehyde from benzen and carbon monoxide, a reaction for which, in th absence of catalyst, there is an increase of free energ of 5 kcal./mole. Evidence was brought forward t show that the aluminium chloride – product com plexes are more stable than the corresponding boro trifluoride complexes, so that if, in the absenc of catalyst, a reaction is thermodynamically un favourable, aluminium chloride has a very gre advantage over boron trifluoride as a catalyst fo that reaction.

As regards the mechanism of these reactions, D Sykes gave evidence for the presence of HCOCl a an intermediate in the reactions catalysed by alum inium chloride. The activation of the other reacta molecule was considered for the case of the formatio of *iso*-butyric acid from carbon monoxide and pr panol. The fact that both normal propanol and *is* propanol react with carbon monoxide to for *iso*-butyric acid suggests that the reaction procee through the formation of an intermediate carboniu ion, since carbonium ions are known to be easil rearranged.

Dr. A. G. Evans read a paper on "Low Temperatu Polymerization" by A. G. Evans and M. Polany The polymerization of *iso*-butene catalysed by boro trifluoride is of great interest because it occurs wit xplosive violence at low temperatures. Owing to e difficulties of studying the kinetics of the *iso*utene polymerization, these authors decided to udy the boron trifluoride catalysed reaction of di-obutene, C_8H_{16}. Under the catalytic influence of oron trifluoride, di-*iso*butene reacts quite readily, ut yields nothing of higher molecular weight than $_{16}H_{32}$. The fact that di-*iso*butene does not polyerize under these conditions, whereas *iso*butene oes, was discussed in terms of steric hindrance. It as shown that steric hindrance in the polymer moleule, which is appreciable even when the monomer *iso*butene, would be prohibitively large for the case f di-*iso*butene. Thus it was assumed that the mechnism of the di-*iso*butene reaction is the same as that f *iso*butene; the absence of a polymerization rection in the case of di-*iso*butene was attributed olely to steric reasons.

To account for the kinetic results obtained, the ossibility of an energy chain-mechanism was disussed. It was suggested that the initiation of the nergy chain is due to the reaction of boron trifluoride ith some component *X*, of which only a trace is resent, to give BF_3X^*, a hot molecule, the energy f formation of which has not been dissipated into hermal energy. In this way, one molecule of the omponent *X* may be effective in causing the rection of many di-*iso*butene molecules. This mechnism would lead to products having a structure imilar to that found for the actual products by infraed examination. It is found that $C_{16}H_{32}$ is not the nly product of the reaction; appreciable quantities f $C_{12}H_{24}$ are also produced. This suggests that the $_{16}H_{32}$ molecules may be capable of disruption nd thus supports the idea of an energy chainmechanism.

Polymerization in the gas phase was discussed by rof. H. W. Melville in a paper on "The Mechanism f Polymerization of Vinyl Compounds". Prof. elville discussed two ways of inducing polymerizaion reactions in the vapour phase: (*a*) by methyl adicals or hydrogen atoms, and (*b*) by photoactivaion. In the case of methyl methacrylate, these two nethods of initiating polymerization chains give rise o reactions which have entirely different kinetics. The most striking difference is that the photoactivated olymerization proceeds in the dark long after the ight is switched off, whereas in the case of the polynerization initiated by free radicals the life-time is f the order of a few milliseconds.

Prof. Melville gave an account of very interesting xperiments on the photopolymerization of vinyl acetate. In the vapour phase the reaction-rate is ressure-dependent, but there is a critical pressure elow which no polymerization occurs. To explain hese results it must be assumed that the photoactivated vinyl acetate molecule may lose its energy pontaneously, that is, in a collision-free process. onfirmation of this hypothesis comes from the fact hat inert gases inhibit the reaction, not by reacting vith the growing polymer, but by interaction with he initially excited vinyl acetate molecules before olymerization starts. This direct photo-polymerizaion is found to be quite a different reaction from that which occurs when the polymerization of vinyl acetate s induced by free radicals.

Prof. Melville described the method by which he as evaluated the individual velocity constants, k_p and k_t, for the propagation and the termination eactions in the vinyl acetate polymerization. By btaining values of the propagation constant at various temperatures, it was found that the activation energy for the propagation reaction is 4,400 cal. and the temperature independent factor is $1 \cdot 48 \times 10^5$ l. mol.$^{-1}$ sec.$^{-1}$ (which means a steric factor of 10^{-6}). For the termination reaction it was found that the activation energy is zero and the temperature independent factor is $2 \cdot 47 \times 10^9$ l. mol.$^{-1}$ sec.$^{-1}$ (which corresponds to a steric factor of 10^{-2}). These experiments have been repeated at double the chain-length, and the results obtained show that the propagation constant k_p decreases only slightly as the molecular size is doubled, and that the ratio $k_p/k_t^{1/2}$ is, to a good approximation, independent of molecular size.

Prof. M. G. Evans concluded the second half of the discussion by reading a paper on "Energy Transfer in Chemical Reactions". Prof. Evans considered the theoretical calculation of steric factors for the propagation and termination reactions of polymerization, and compared the values obtained in this way with those found experimentally by Prof. Melville. He showed that the steric factor for propagation given by the transition state theory is of the same order as that which is found experimentally. In the case of termination reactions, however, the theory is unable to interpret the experimental results. He suggested that the possibility of an energy chain (in which the growing polymer molecule is always energetically active at the terminal double-bond) might be understood if it be assumed that an active double-bond is one that is in the triplet state. In this case the resonance requirements in the transition state for the addition of a molecule of monomer to the end of an active polymer may result in the double-bond of the added monomer being converted into the triplet state, and thereby activated.

A. G. Evans.

IMPEDANCE BRIDGE WITH A 10^9 TO 1 RANGE

For measuring the impedances of a wide variety of coils used in electronic and communication apparatus the Bell Laboratories have designed a wide-range audio-frequency bridge, and a carrier-frequency bridge, about twenty-five of which have been constructed for the various manufacturing plants of the Western Electric Company. The bridges have been described in an article by H. T. Wilhelm (*Bell Lab. Rec.*, 23, No. 3; March 1945).

The audio-frequency bridge can measure inductance from one microhenry to 1,000 henrys, and resistance from 0·001 ohm to 1 megohm. This extremely wide range is secured by providing six component ranges, any one of which may be selected by operating a single range dial. Depending on the position of this dial, the normal reading of the bridge is multiplied by 0·01, 0·1, 1·0, 10, 100, or 1,000. The frequency range of the bridge is from 20 to 10,000 cycles. One arm (*AB*) includes a conductance and a capacitance standard in parallel, each controlled by four dials. A six-position range dial selects resistors for the two resistance arms (*BC* and *AD*) that will result in the desired multiplying constant. Six resistors in the *AD* arm and three in the *BC* arm are used for this purpose. The inductance component of the impedance under test is determined by the capacitance standard, and four dials which control this standard are marked directly in terms of inductance, ranging from steps of 0·1 henry at the left to 0·0001 henry at the right. The latter dial gives continuous control of the standard, and thus values may be estimated to one tenth of a step or 0·00001 henry.

The carrier-frequency bridge is almost identical in appearance with the audio-frequency bridge. It covers the frequency range 20–150,000 cycles and differs from the audio-frequency bridge principally in the detector transformers, and in the capacitance and conductance standards. The carrier capacitance decade steps are one tenth those of the audio bridge, and the carrier conductance decade steps are ten times those of the audio bridge. It is designed for test potentials up to 100 volts and currents up to 0·2 amp. A greater assortment of zero-impedance compensators is provided to permit zero balances to be made for all measurements. The accuracy of measurement for both audio and carrier bridges is of the order of 0·25 per cent for the major component of the impedance, and a slightly wider limit of accuracy is attained for the minor component.

Without changing its size or general appearance, it was found possible by the addition of a few circuit elements to adapt this bridge to measurements of capacitance as well as of inductance. Such a bridge therefore is also available in both the audio-frequency and carrier-frequency range. Inductances are measured exactly as with the bridge described above; but for capacitance measurements, the circuit is changed to a ratio-arm comparison bridge.

In designing the wide-range impedance bridge, it was found that no detector was available that would operate over the desired range of frequency and give the high sensitivity needed, and still be suitable for use in manufacturing plants where sizes, ruggedness and easy manipulation are of prime importance. It was therefore decided to employ a cathode-ray detector, which has certain advantages where many similar units must be tested. An additional amplifier and detector tube was also incorporated, connected to a meter jack to provide for situations where it might be desired to use a meter indication. Two detectors were made, one for the audio range and one for the carrier range, and these are described in an accompanying article by E. H. Eveland.

With an A.C. bridge, the signal delivered to the detector will in general contain a number of components in addition to the fundamental frequency of the oscillator. These may be harmonic frequencies of the oscillator, harmonics generated by the non-linear characteristics of the unknown, and noise picked up or generated by the system. The oscillator fundamental is balanced out by the bridge; but if a good null detection is to be obtained, provision must be made for eliminating or greatly decreasing the undesirable components. To avoid the use of filters, feedback amplifiers are employed in the detector to reduce all components but the oscillator fundamental.

In the circuit employed for the new detector, a buffer amplifier receives the output from the bridge and has sufficient feedback to prevent cross-modulation of the harmonics that would generate the oscillator frequency as a component in its output. From this amplifier the signal passes through a three-stage amplifier with selective feedback that gives at least 40 db. greater gain for the fundamental than for any other component present. From this feedback amplifier, the signal passes to a single-stage amplifier with automatic volume control, and thence to the vertical plates of the cathode-ray tube. A connexion is also carried from the automatic volume-controlled amplifier to another amplifier and detector to supply an indicating meter when one to be used instead of the cathode-ray tube. To suppl the horizontal plates of the cathode-ray tube, a sign from the oscillator is first passed through an invert to change the unbalanced output of the oscillator t the balanced input required by the cathode-ray tub The output of the inverter is then carried through phase-shifting network, and thence through a amplifier to the horizontal plates of the cathode-ra tube. The network permits the phase of the voltag applied to the horizontal plates to be shifted relativ to that applied to the vertical plates so that an ellips is obtained on the cathode-ray tube. The use of automatic volume control avoids the need of frequentl adjusting the detector gain as the bridge is bein balanced, and it greatly expedites the work when no even the approximate value of the coil under test i known.

While the bridge is unbalanced, the image on th cathode-ray tube is an ellipse with the shorter axi proportional to the resistance unbalance, and wit the angle between the longer axis and the horizonta axis of the tube proportional to the inductance unbalance. The size of the angle made by the longe axis of the ellipse indicates the amount of the unbalance, while the direction of unbalance is indicate by this angle being above or below the horizontal At balance, the ellipse collapses to a horizontal line

One of the purposes in designing the new detecto was to permit rapid tests to be made, or large number of similar coils having nominal values of inductanc and resistance which must be met within certai limits to be acceptable. To determine quickl whether or not the coils meet the requirements, thin cellulose acetate plate marked with limiting line is placed over the end of the cathode-ray tube. Th bridge dials are set to the nominal values of inductanc and resistance of the coils, which are then connecte to the bridge, one after another, and, if the ellipse appearing on the tube lie within the acceptance value as indicated, the coils are accepted. The two detector available are similar in appearance and circui arrangement, but one covers the frequency rang 20–20,000 cycles and the other 200–200,000 cycles Twenty of these bridge-detector units are now in us for testing coils in the various manufacturing plant of the Western Electric Company.

VOLCANOLOGICAL STATION OF KAMCHATKA

A BRIEF report by V. I. Vlodavetz on the activit of the volcanological station of Kamchatk (*Bull. Acad. Sci. URSS.*, Sér. Géol., No. 1, 40 1945) provides some interesting information regarding this little-known volcanic region. About 40 pe cent of the total surface of Kamchatka is occupie by Quaternary and Recent lavas and tuffs, and a the present time the total number of known volcanoe is 129, of which twenty are either active or dormant There are also sixty-eight groups of thermal spring and seventeen large geysers. The volcanoes ar arranged along two belts, one extending 700 km along the eastern margin of the peninsula, the othe along the middle ridge. The most prominent activ volcano is Klyuchevskaya Sopka, which during th last two hundred and forty years has erupted fift times.

asual observations of Kamchatka's volcanoes gan in the first half of the eighteenth century, t it is only since 1931 that a systematic study has n made, beginning with the publication of a report the Avacha volcano by A. N. Zavaritzky. In 35, through the initiative of F. Y. Levinson-ssing, a volcanological station was built in the inity of Klyuchevskaya Sopka. After the death Levinson-Lessing in 1939, the station was directed A. N. Zavaritzky, who is now organizing a special lcanological Laboratory in Moscow. The principal rposes of the Volcanological Station are systematic servation of volcanic activity, the study of volcanic oducts such as lavas, ashes, gases and sublimates, d the study of thermal springs and geysers. The ation consists of several buildings, including chem- l and petrographical laboratories, library and ing quarters, and is staffed by a number of servers who have at their disposal horses in the mmer and sledge-dogs in the winter.

The principal observations made at the Station fer to Klyuchevskaya Sopka. During the last ten ars, it has had two periods of eruptive activity: ugust–October 1935 and April 1937–March 1939. he total volume of lavas and ashes erupted amounted 437 millions cubic metres. A rough calculation ows that the volume of the present cone corresponds the product of seven hundred eruptions of equal tivity, and the estimated age of the volcano is five ousand years. Another interesting observation ade during the last stage of volcanic activity relates the composition of lavas. The lavas erupted at the wer level correspond to olivine-basalts, and those om the upper level to andesite-basalts; this ggests a gravitational differentiation within the lcanic pipe.

A remarkable feat was achieved by V. F. Popkov d I. Z. Ivanov, who, perched for one hour on a ating raft of solid lava, drifted along the flowing va for a distance of 2 km. During this drift they ere recording the temperature of the lava and llecting samples of gases. The recorded temperares of the flowing lava varied between 870° and 0° C., and the amount of gases in the lava was ry high. According to Popkov, 196 million cubic etres of gases (mainly steam) were emitted by lyuchevskaya Sopka during the intensive phase of tivity, while the neighbouring crater of Bilukay as emitting 1,200,000 cubic metres per hour. ccording to S. I. Nabokov (*Bull. Acad. Sci. URSS.*, r. Géol., No. 1, 501; 1945), the volcanic gases consist mainly of steam with variable amounts of hydroloric and hydrofluoric acids, sulphur dioxide, carbon onoxide and dioxide, methane, ammonia, hydrogen, ygen and nitrogen. The fumaroles can be subivided into two main groups, chloridic and sulphic, and the first group in its turn can be subdivided to (1) hydrous (800°), (2) halitic (500°), (3) mixed 00°–800°), (4) ammoniac (300°) and (5) fluorine elow 200°). Altogether forty-six chemical elements ve been recorded among the volcanic sublimates, well as several new minerals as yet unidentified.

It has recently been reported that Shiveluch, the ost northerly volcano in Kamchatka, has begun upting. A pillar of incandescent gases rising to a ight of two miles and at night visible thirty miles way has already been reported.

The results of observation of Kamchatka's volcanic tivity are now published in the *Bulletin of the olcanological Station on Kamchatka*, which began iblication in 1937, as well as other periodicals. In the *Bulletin of the Russian Geographical Society* of 1932, a map of volcanoes was published by N. G. Kell and a catalogue of volcanoes by P. T. Novograblenov. Among A. N. Zavaritzky's works dealing with Kamchatka, the most important are those relating to the rocks of Klyuchevaskaya Sopka (1931), to the northern group of volcanoes (1935) and the Avacha volcano (1935).

S. I. TOMKEIEFF.

REORGANIZATION OF MUSEUMS IN FRANCE

OF considerable interest is a short article entitled "Museum Reorganization in France", which appears in the *Museums Journal* of September (pp. 95–96). It reports the adoption of a scheme for the extensive reorganization of the art, history, and archæological museums of that country. The scheme will operate under the new Directorate of Arts and Letters which (by order of the French Minister of Education) has now replaced the former Directorate of Fine Arts. The development of the new Directorate (under M. Jacques Jaujard) will include the national museum service (hitherto known as "Musées nationaux"). In future, this service is to be known as "Musées de France", and it will be responsible for not only the six departments of the Louvre, the Palais de Tokio, the Jeu de Paume, the Guimet and Rodin Museums, and the museums of Cluny, Versailles, Saint-Germain, Compiègne, Sèvres, Malmaison, Fontainebleau, Pau, etc., as in the past (under its former designation), but also for all the provincial art museums. The object of this is the improvement of provincial museum collections, and the extension to those institutions of modern museum methods. A General Inspectorate of Museums, under the control of the Director of French Museums, will ensure maintenance of efficiency in these respects. In addition, the provincial museums are to be divided into two categories: (1) designated museums, and (2) controlled museums. The former will comprise the more important institutions (the curators of which will be Government officials), and the latter the smaller museums, the officials of which will remain municipal employees. In the first case the payment of salaries will be shared between the State and the municipalities concerned; in the second case, presumably, there will be no State grant in respect of salaries, but the Government will reserve the right of selecting candidates, and these, as a rule, will be required to hold the higher diploma of the École du Louvre.

It is made clear that these developments do not mean the nationalization of French museums; but they do mean that, from now on, the Government will exercise new powers over them with the view of their improvement and development. Scientific museums (those of natural history, chiefly) are not specifically mentioned in the plan, but their coordination with those that are specified is ensured in view of the fact that they are represented on various commissions, and that the French association of curators of public collections covers those commissions concerned with both types of museums.

Other branches of the new Directorate of Arts and Letters will deal with libraries, archives, etc., drama and music, and literature, and "another great department will be that of Architecture, including town planning and reconstruction".

FORTHCOMING EVENTS

*(Meeting marked with an asterisk * is open to the public)*

Saturday, November 24

Institution of Mechanical Engineers, Graduates' Section (at Storey's Gate, St James's Park, London, S.W.1), at 3 30 p.m.—Mr. A. C. Hartley: "Operation PLUTO" (Annual Lecture).

Monday, November 26

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C 2), at 1 45 p.m.—Dr. F. C. Bawden: "Virus Diseases of Plants", 2. "The Spread of Virus Diseases" (Cantor Lectures)

Institution of Electrical Engineers (at Savoy Place, Victoria Embankment, London, W C.2), at 5 30 p.m—Discussion on "Standardization of Ripple Control" (to be opened by Mr. T. R. Rayner).

Society of Chemical Industry (joint meeting of the Plastics Group with the Institution of the Rubber Industry, in the Great Hall, Caxton Hall, Victoria Street, London, S.W 1), at 6.30 p m. —Mr. S. J. Skinner· "Synthetic Polymers in the War Effort".

Chemical Society, Yorkshire Section (in the Chemistry Lecture Theatre, The University, Leeds), at 6.30 p.m.—Prof. E. D. Hughes. "Substitution" (Tilden Lecture).

Royal Geographical Society (at Kensington Gore, South Kensington, London, S.W.7), at 8 p m.—General Sir William Platt. "The Geography of the Campaign in Eritrea and Northern Ethiopia".

Tuesday, November 27

Society of Chemical Industry, Agriculture Group (in the Physics Lecture Theatre, Royal College of Science, Imperial Institute Road, London, S.W 7), at 2.30 p.m.—Mr. D. H. F. Clayson: "The Chemistry of Composts".

Royal Anthropological Institute (at the Royal Society, Burlington House, Piccadilly, London, W 1), at 5 p m.—Prof. A. R. Radcliffe-Brown: "Religion and Society" (Henry Myers Lecture).

Royal Institution (at 21 Albemarle Street, London, W 1), at 5.15 p m.—Dr. Kathleen Lonsdale, F.R.S.: "Recent Research Work in the Davy Faraday Laboratory", (ii) "Divergent Beam X-Ray Crystallography".

Institution of Electrical Engineers, Radio Section (at Savoy Place, Victoria Embankment, London, W.C 2), at 5 30 p m—Discussion on "Film Forming Materials used in Insulation" (to be opened by Mr. C. R. Pye).

Quekett Microscopical Club (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 6 p m—Gossip Meeting; Mr. F. E. J. Ockenden: "Illuminants and Illumination".

Society of Chemical Industry, the Royal Institute of Chemistry, and the Chemical Society (joint meeting of the Edinburgh and East Scotland Sections with the Edinburgh University Chemical Society, in the Biochemical Lecture Theatre, Teviot Place, Edinburgh), at 7 p.m.—Prof. G. D. Preston· "The Structure and Chemistry of Metallic Crystals".

Sheffield Metallurgical Association (at 198 West Street, Sheffield 1), at 7 p.m.—Dr. R. Hunter: "Some Problems on the Heat Treatment of Steel".

Iron and Steel Institute (joint meeting with the Lincolnshire Iron and Steel Institute, at the Scunthorpe Technical School, Cole Street, Scunthorpe), at 7.30 p.m.—Dr. H. L. Saunders and Dr. H. J. Tress "Sinters and Sintering", Part 1.

Wednesday, November 28

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Mr. James Agate: "A Moment in the History of the English Theatre" (Peter Le Neve Foster Lecture)

Institute of Physics, Electronics Group (at the Royal Institution, 21 Albemarle Street, London, W.1), at 5.30 p m.—Mr. A. J. Maddock: "Dielectric Heating".

Institute of Welding (at the Institution of Civil Engineers, Great George Street, London, S W.1), at 6 p.m.—Dr. H. O'Neill· "Metallurgical Features of Welded Steel".

Society of Public Analysts and other Analytical Chemists, Physical Methods Group (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6 p m.—Annual General Meeting: Mr. R. C. Spiller: "The Barker Index—a Means of Identifying Crystals from their Shape"; Dr. M. W. Porter and Dr. A. E. J Vickers: "Examples of the Utility of the Barker Index in Analytical Chemistry".

British Institution of Radio Engineers (in Reynolds Hall, College of Technology, Sackville Street, Manchester), at 6.15 p.m.—Discussion on the Radio Industry Council Report on "Post-War European Broadcasting".

Royal Institute of Chemistry, Tees-side Local Section (at the Wm. Newton School, Norton, Stockton-on-Tees), at 7 15 p.m.—Mr. A. L. Bacharach. "Recent Developments in Vitamin Biochemistry".

Thursday, November 29

Chadwick Public Lecture (in the Sir Edward Meyerstein Lecture Theatre, Westminster Hospital Medical School, 17 Horseferry Road, London, S.W.1), at 2 30 p.m.—Dr. Archibald M H. Gray· "Some Social Aspects of Industrial Dermatitis" (Malcolm Morris Memorial Lecture)*.

Chemical Society (joint meeting of the Nottingham Section with the University College Physical and Chemical Society in the Chemistry Lecture Theatre, University College, Nottingham), at 4 p.m.—Prof. W. Wardlaw: "Structural Inorganic Chemistry".

Royal Institution (at 21 Albemarle Street, London, W.1), at 5.15 p.m.—Sir James Jeans, O M., F.R.S: "Physical Astronomy", (i) "The Cold Matter of the Planets".

Association for Scientific Photography (at the Alliance H Westminster, London, S.W.1), at 6.30 p.m.—Mr. Alan G. Sab "Some Notes on Illumination in Photomicrography".

Society of Chemical Industry, East Midlands Section (at Corporation Gas Theatre, Nottingham), at 7 p.m.—Mr. W. Wilso "Electronics with special reference to Detection, Measurement a Microscopy".

Friday, November 30

Royal Institution (at 21 Albemarle Street, London, W.1), 5.15 p.m.—Sir Nelson Johnson, K.C.B.: "Recent Advances Meteorological Methods".

Institution of Mechanical Engineers (at Storey's Gate, James's Park, London, S.W.1), at 5.30 p.m.—Discussion on "Pist and Piston Rings" (to be opened by Mr. J. S. Courtney-Pratt, G. K Tudor and Dr. B. Pugh).

North-East Coast Institution of Engineers and Shipbuild (in the Lecture Theatre, Mining Institute, Newcastle-upon-Tyn at 6 p m.—Dr. R. S. Silver and Mr. J. A. Mitchell. "Flow of Boil Water through Tubes and Orifices".

APPOINTMENTS VACANT

Applications are invited for the following appointments on before the dates mentioned.

Teacher of General Engineering Subjects (including El trical) at the Bootle Municipal Technical College and Boys' Second School (Trinity)—The Director of Education, Town Hall, Boo (November 30).

Chief Electrical Engineer to the Hammersmith Metropolit Borough Council—The Town Clerk, Town Hall, Hammersmith, L don, W.6 (November 30)

Assistant Lecturer in Physics—The Registrar, Municipal Coll of Technology, Manchester (November 30).

Head of the Department of Mathematics and Physics, He of the Department of Pharmacy, a Lecturer in Electric Engineering (preferably with teaching and industrial experienc a Lecturer in the Department of Mathematics and Physi and a Lecturer in Chemistry (able to teach Organic Chemistry Degree standard)—The Registrar, Municipal College, Portsmou (December 1).

Laboratory Steward in Biology in the Department of Che istry and Biology—The Clerk to the Governors, South-East Es Technical College and School of Art, Longbridge Road, Dagenha Essex (December 1).

Assistant Lecturer (woman) in Chemistry and Tutor Women in the Bradford Technical College—The Director of Educatio Town Hall, Bradford (December 1)

Assistant Librarian—The Registrar, University College, Nottin ham (December 3)

Junior and Senior Physicist for research on electronics, a Junior and Senior Physicists or Engineers for work on hig frequency and vidio-frequency circuits, by Research Laborator engaged mainly on Television—The Ministry of Labour and Nation Service, Appointments Department, Technical and Scientific Regist Room 670, York House, Kingsway, London, W.C.2, quoting A.1121.X (December 4).

Waterworks Engineer and Manager—The Clerk to the Spaldi Urban District Council, 11 Market Place, Spalding, Lincs. (December

Civil Engineers (two) by the Government of Iraq for the Direct ate General of Irrigation—The Ministry of Labour and Natio Service, Appointments Department, Technical and Scientific Regist Room 670, York House, Kingsway, London, W.C 2 (December 7).

Statistician in the Department of Preventive Medicine—T Secretary, Welsh National School of Medicine, 10 The Parade, Card (December 8).

Engineer and Manager of the Nottingham Corporation G Undertaking—The Town Clerk, The Guildhall, Nottingham, endors 'Engineer and Manager, Gas Undertaking' (December 15)

Lecturer in Charge, Sheep and Wool Department, Sydn Technical College—The Acting Official Secretary, New South Wa Government Offices, 125 Strand, London, W.C.2 (December 31).

Lecturer in Coal Utilization and Fuel—The Secretary, T University, Edmund Street, Birmingham 3 (December 31).

Lecturer in Civil Engineering (Ref. No. E.3025.XA), and Lecturer (permanent) and a Lecturer (temporary, two yea (Ref. No. C 2924 A), in the University of Cape Town—The Minist of Labour and National Service, Appointments Department, Techni and Scientific Register, Room 670, York House, Kingsway, Lond W.C 2, quoting the appropriate Ref. No. (January 12)

Lecturer in Geography in the University of Cape Town—T Ministry of Labour and National Service, Appointments Departme Technical and Scientific Register, Room 670, York House, Kingswa London, W C.2, quoting F 5188.A (January 12).

Civil Engineer by British Contractor to take charge of section large construction job in Middle East—The Ministry of Labour a National Service, Appointments Department, Technical and Scient Register, Room 670, York House, Kingsway, London, W.C 2, quoti E 3009 XA (January 12).

Secretary to the Curators of the University Chest—The Secreta to the Curators of the University Chest, Oxford (January 31)

Lecturer in Histology, a Lecturer in Pharmacology, Lecturer in Embryology, and a Lecturer in Civil Engineer —The Secretary, Queen's University, Belfast (March 31).

Assistant in the Department of Economics for Milk Co Investigation work—The Secretary, South-Eastern Agricultu College, Wye, Ashford, Kent.

Lecturer (temporary) in the Civil and Mechanical Enginee ing Department, for courses leading to the London Univers Degree, with Structures as one of the main subjects—The Secreta Woolwich Polytechnic, Woolwich, London, S.E.18.

A STATE SCIENTIFIC SERVICE IN BRITAIN

IN recent weeks the general public has learnt a great deal more of the scale and importance of the contribution made by scientific men, in the Government service and outside it, to the war effort. In the developments leading to the atomic bomb, radar and numerous other fields, the significance of that contribution, both in peace and in war, is now far more widely appreciated, and Lord Hankey in his recent book, "Government Control in War" stressed the need for organizing more effectively something of a Scientific Civil Service. The White Paper under that title which has now appeared[1] deals with the reorganization and recruitment of that Service during the reconstruction period. It falls into three parts. The first part outlines the Government proposals for effecting the reorganization of the Scientific Civil Service. The second part deals with questions of recruitment to the scientific service during the reconstruction period, which were left undetermined in the White Paper dealing with the administrative, executive and clerical classes last November. The core of the present White Paper, however, is the annex containing the report of the Barlow Committee on Scientific Staff. This report, dated April 23, 1943, is appropriately considered first. In general, it may be said that it fully substantiates much of the criticism of the conditions of service of scientific men in Government departments which found expression in debates in the House of Lords and the House of Commons and elsewhere.

The Committee, over which Sir Alan Barlow presided, consisted of Sir Edward Appleton, Mr. W. F. Lutyens and Prof. E. K. Rideal, and was asked to consider in particular the comparison between the initial salaries of administrative and scientific entrants; the question whether the existing conditions of service for scientific workers provide adequate prospects for the average entrant; and whether sufficient facilities exist for free interchange of scientific personnel, and in particular research men, between the Government service on one hand, and the universities, industry and outside bodies in general on the other. Inquiries were confined in the main to the Defence Departments and the Department of Scientific and Industrial Research: the Committee did not regard the engineering or medical services as coming within its scope. The Committee, however, sets out what it regards as the essential principles which should be followed to secure a higher standard of recruitment into, and so raise the general level of, the scientific establishments of the Government service, and emphasizes that it is essential that its recommendations should be implemented at the earliest possible opportunity, without waiting for a fuller post-war inquiry. It will be recalled that the present terms of service of scientific staff derive from the recommendations of the Carpenter Committee which reported in 1930, and that although those recommendations were endorsed by the Royal Commission on the Civil Service, they were not brought fully into operation until 1936.

All the evidence before the Barlow Committee points to the main conclusion that the Government failed in peace-time to attract into, and retain in, its service a proper proportion of the best scientific workers produced by the universities of Britain. The fault seems, to the Barlow Committee, to lie partly in the standards of remuneration and the prospects of promotion offered, but at least as much in general conditions of service and the relations between Government research organizations and the scientific world outside. In general, for scientific workers of average ability, of whom any large scientific organization is bound to require a substantial number, Government employment offers prospects, up to a certain level, which compare not unfavourably with those offered in most universities and in industry for men of like ability, and at present the Committee has no special comments to offer on the pay and prospects of such workers. It is in regard to the man of more than usual ability that improvement is necessary, and the Committee is emphatically right when it lays down as a first essential that the scales and system of promotion of the scientific classes should ensure that the best scientific men should have equal prospects of pay and promotion with the best men in the administrative class at least up to the top of the grade of 'principal'. The Government's present proposals in this connexion, taken in comparison with those relating to the salaries and organization of the administrative class, are criticized by the Institution of Professional Civil Servants in a pamphlet entitled "A New Deal for Government Scientists ?"[1]; for the outstanding scientific man would still be well below the outstanding administrator in salary level, and neither the average nor the outstanding scientific officer has been given parity with administrative officers.

In devoting the major part of its report to this question of attracting to the service of the State a proper proportion of the ablest men of science coming from the universities, the Barlow Committee is clearly in harmony with general opinion in Britain as revealed in discussions on the organization of scientific and industrial research during the last two years. Dealing first with remuneration, the Committee points out that there has been some divergence of practice between departments in implementing the Carpenter Report, and it considers that departments should be prepared to offer initial salaries above the minimum of the junior scientific officer scale to candidates who have spent one or two years in postgraduate research. The existing provisions for recruitment direct into the grade of 'scientific officer' could also be utilized, and there should be regular recruitment to that grade at a later age by means of an examination similar to that applied by the 1851 Commissioners.

Evidence submitted to the Committee was unanimous as to the necessity of providing rapid advancement for outstanding men, and the Committee recommends that the existing authority to give special advances within the scale to a limited number of officers should be extended. The problem of securing rapid advancement beyond the grade of 'scientific officer' for the outstanding scientific work is primarily that of so regulating the proportion higher to lower posts as to ensure reasonable pro pects of promotion. The outstanding man shou be able to reach the grade of 'principal scientif officer' in the early thirties, and to this end tl Committee recommends full use of the Carpent Report recommendation under which such promotic should be made by reference to outstanding individu work, even if the research officer is lacking in capacit for organizing and directing the research work others. While the Treasury should be ready authorize special additional posts, in return tl Treasury might require that the nomination f any such post should be approved by the Inte Departmental Scientific Panel, establishment which is recommended to maintain a uniform stan ard for such special advancements and promotio and to improve administrative liaison between tl departments. Moreover, any step which assists tl heads of scientific departments to a fuller knowled of the work done in other departments would itself be of value.

Beyond this, in regard to remuneration, the Com mittee also recommends that the salaries of tl highest posts on the scientific side of the Governme service should be increased. This would also hav the effect of narrowing the gap between the pay such posts and that of the highest posts on tl administrative side ; but the Committee goes furth and urges consideration of the possibility of mo frequent transfers of suitable men of science to tl administrative class. Here it raises a fundament issue the importance of which has been widely reco nized already in comment on the White Paper. It not merely that the report challenges the whole id that the scientific worker as such is by training ar outlook inherently unfitted for high administrati office. When the Barlow Committee recommen that the provision of special machinery to ensu that scientific workers serving in departments wit out any administrative cadre of their own should considered for transfer to administrative vacancies other departments, it is not merely thinking of ope ing up wider avenues of promotion for men of scienc it has equally in mind the benefit to Governme business from the introduction of a different outloo particularly in departments where the work is co cerned with scientific and technical processes.

This broadening of the basis of recruitment to tl highest posts in the administrative class of the Ci Service is of the utmost importance to enable t Civil Service to become competent to deal with t affairs of the post-war world ; and it is to be hop that neither this point, nor the corollary of the fre admission of scientific men to posts where th exercise more and more influence over social planni and administration—that men of science themselv must be more adequately trained in the humanit and cultural subjects and early specialization avoid —will not be overlooked in the debate which is lik to ensue on the White Paper. It would indeed b tragedy if the Institution of Professional Ci Servants, which seems to have misconstrued co etely the Barlow Committee's concentration on the provement of the conditions for the outstanding an of science, failed to lend the weight of its support proposals of the highest significance from the ational point of view.

We can find in the Barlow Report no substantial undation for the suggestion, indignantly and rightly pudiated by the Institution, that existing scientific affs are inferior in quality to their colleagues outde the Government service. That is no valid deuction from the conclusion that the Government rvice in peace-time did not attract and retain a fficient proportion of the best men of science coming om the universities of Britain; and in the important ction of its report dealing with general conditions f service, the Committee's observations are pertinent the average as well as to the outstanding scientific ficer. Moreover, it recognizes clearly that there ould be the closest contact between research and velopment, and that a high standard of recruitent is as necessary on the development as on the search side. It makes indeed no firm recommendaon as to the continued distinction between the ientific and technical grades, but is of the opinion at the designation 'chemist' might be discontinued nd the present long salary scales for technical fficers and chemists divided into two.

One of the dangers to which a Government scientific ranch is inherently liable is the tendency towards olation from the rest of the scientific world. This detrimental both to their work and to recruitment, ad to overcome that tendency the Barlow Committee akes various suggestions. Extra-mural research ntacts are of great benefit, and heads of scientific epartments should try constantly to improve concts with both university authorities and students. emporary interchanges of staff with the universities, ecial leave with pay to attend scientific meetings ad conferences, as well as exchanges of staff with dustry, direct contact between Government scienfic branches, especially in administration, and ansfers of scientific staff from one department to nother are desirable; though research workers ould, wherever practicable, remain associated with rojects which they themselves have started. It oes not recommend, however, a unified State cientific Service with a single establishment and sponsible to a common head. Great importance is ttached to the introduction of a scheme on the nes of a 'sabbatical year', under which selected ientific staff would be allowed special leave to work a university or other institution in Great Britain abroad, and attention is directed to the desirability locating research establishments so far as possible ithin easy reach of a university or intellectual centre ad in close proximity to other establishments workg on kindred problems. Direct contact at all levels etween the staffs of different establishments should e made easy.

One of the greatest disadvantages of the Governent scientific service is the extreme emphasis upon crecy. This both makes it difficult or impossible r the Government worker to enter into discussion th similar workers outside, and also prevents his obtaining recognition in the scientific world of the value of his work. Such conditions are not only a formidable barrier to recruitment but also to scientific work itself, by hindering the fertilization or stimulation of new ideas; and it is satisfactory to note from the White Paper that the Government views sympathetically the recommendation that secrecy restrictions should be as much as possible relaxed, and scientific workers encouraged both to publish work of their own and to discuss their work with persons outside the service engaged on similar problems. Furthermore, the Government particularly approves the Barlow Committee's recommendations for dealing with this tendency to isolation, and proposes that one of the first tasks of the new Interdepartmental Scientific Panel should be to consider how they can be implemented.

With regard to secrecy, the Barlow Committee suggests as a solution that it should not be assumed as a matter of course in peace-time that the whole of the work of a research establishment must automatically be regarded as secret; matters of fundamental research should be regarded as *prima facie* suitable for discussion with outsiders, and the questions on which absolute secrecy is prescribed should be kept to the minimum. The head of a research establishment should have discretion, and be encouraged to allow his staff to discuss their work confidentially with members of outside institutions who are engaged on similar problems, and a system should be possible whereby members of the staff engaged on secret work could submit theses for higher degrees. Fuller use might be made of advisory councils to secure professional recognition of the work of Government scientific workers, and lectures by eminent men of science and 'colloquia' should be encouraged, and adequate lecture-rooms, libraries and workshops provided. Finally, the Committee points out that control of civilian scientific staffs by uniformed officers tends to be prejudicial. Uniformed officers should act as advisers on behalf of the user services rather than as direct controllers of research and development. Further, heads of laboratory units should have more freedom in procuring equipment.

No scientific worker will mistake the importance of the Barlow Committee's Report or the weight of the support it brings to policies and principles that have long been advocated in these columns. It is the more satisfactory to find that many of the recommendations of the report have been accepted by the Government and incorporated in the Government's proposals, which in some respects go beyond those of the Committee. Moreover, the White Paper points out that the investigation of these questions had begun under the Coalition Government, which was equally resolved on the reorganization of the scientific service; and it may therefore be hoped that consciousness of the contribution made by science towards winning the War, and of that which science can make during peace to the efficiency of production, to higher standards of living, to improved health and to the means of defence, is shared by all political parties.

The Government proposes to establish an Interdepartmental Scientific Panel, of which Sir Edward

Appleton will be chairman, with the further responsibility of keeping under review the well-being and efficiency of the Government scientific service. It will also make proposals for any desirable changes in the organization or conditions of service necessary to this end, in addition to that proposed by the Committee of maintaining a uniform standard for promotions and special advancements and improving administrative liaison between departments. In order that pension arrangements may not constitute a barrier to interchange of staff with the universities, almost all scientific officers in the permanent service of the Government will be brought under the Federated Superannuation Scheme for the Universities. The salaries of the most highly qualified members of the scientific service are to be brought into relationship with those of the administrative class, and at the recruitment stage they are to be aligned to them. Special provision will be made for recruiting, above the normal minimum salary, university graduates with research experience, and also for recruiting direct to grades above basic, scientific workers who possess special qualifications or experience which a department requires.

The Government has also accepted the recommendation that ultimate prospects should be improved, including provision for the promotion, above the level of 'principal scientific officer', of individual research workers of exceptional ability, without necessarily expecting them to carry administrative responsibility. Furthermore, the present class of 'assistant' is to be strengthened, re-named the 'experimental officer' class and more fully used, much of the work at present done by scientific officers being devolved on scientific assistants. There will be provision for promotion from this class to the scientific officer class under conditions which will be considered later by the Scientific Panel; but the Government also proposes a provincial differentiation in salary scales, to which the Institution of Professional Civil Servants has already objected and which may well be the subject of wider and reasoned criticism. It is proposed to recruit the whole of the scientific service centrally through the Civil Service Commission, and with this in mind Dr. C. P. Snow's name will be submitted for appointment as additional Commissioner with special responsibility during the reconstruction period for the recruitment of scientific and experimental officers.

This scheme of reorganization applies to staff employed directly by Government departments, but the adaptation of these arrangements to suit the needs of the staff employed by other institutions working under the ægis of the Medical Research Council, for example, the Agricultural and Fishery Departments and the Development Commission, is now under consideration. Finally, in the second part of the White Paper, there are set forth the lines on which it has been agreed with the national staff side of the Whitley Council that the general principles outlined last year in the White Paper "Recruitment to Established Posts in the Civil Service during the Reconstruction Period" can best be applied in the scientific field, and in accordance with which recruitment will be carried out. These conditions includ the restoration of open competitions for entry to th Scientific Civil Service as soon as possible, with specia reconstruction competitions over a period, publication of full particulars throughout the Forces, wit arrangements to ensure that any possible candidate serving in Europe or the Far East have an opportunity of being considered, and provision for retention in a permanent capacity of specially selecte senior temporary officers, above the maximum ag allowed in the open reconstruction competitions, wh possess exceptional ability or experience, as well a for retention in the basic grade of assistant experimental officer of a proportion of the best of the temporary officers, above the age of thirty, in the existin grades of Assistant II and Assistant III.

The Institution of Professional Civil Servants ha published, in the pamphlet already mentioned, a careful analysis of the new scales—those for the administrative class are outlined in a further White Pape published simultaneously—which shows that both fo scientific officers and experimental officers the ne careers should be a considerable improvement on th old. The outstanding scientific officer would have career roughly equivalent to that of the good averag administrator, but the average scientific officer woul compare unfavourably with his administrative colleague. Apart from the question of provincia differentiation introduced for scientific men for th first time, the Institution's main objection to the proposed scales is that the scheme still leaves the scientifi worker in a position inferior to that of his administrative or executive colleague. There are further detail in regard to superannuation and the application o the scales on which discussions are proceeding, bu the Institution clearly recognizes that there is fo the first time to be a real Government Scientifi Service, recruited centrally through the Civil Servic Commission, instead of a haphazardly recruited serie of departmental classes. Nevertheless, to meet th widely varying qualifications of scientific workers, th grading will have to be interpreted broadly, and th proposed Interdepartmental Scientific Panel mus approach its task in no niggardly spirit.

Whatever criticism may be advanced in matters o detail, there can be no doubt that the whole schem represents a definite advance in recognition of th value of the scientific worker, and it is clearly th outcome of much sympathetic thought, practic knowledge and experience. Moreover, in certai features, such as the provisions for superannuatio and a sabbatical year, publication of results and th like, which encourage mobility of staff and the inte change of thought, it may well make a contributio to the stimulation of scientific and industrial advanc far beyond the bounds of the Government servic Such features call for close and sympathetic study b industry as well as by the universities in order t realize the full effect of the recommendations of t Barlow Committee.

To recognize this is not to suggest that the ne proposals provide all that is required. They represe indeed substantial recognition of the fact that Government without an adequate staff of scienti workers is properly equipped to direct the affairs of a modern country pervaded by scientific technique, especially when the range of Government control over industry and economic life tends to grow. But they do not in themselves indicate that there is any real appreciation that the administrator himself, be he Civil servant or Minister, requires some appreciation of the scientific outlook, some basic understanding of science itself, if he is to handle competently issues of State into which scientific and technical factors ncreasingly enter.

To that extent scientific workers generally will be at one with the Institution of Professional Civil Servants in refusing to be content with any scheme which leaves the man of science in a position inferior o that of his administrative or executive colleague. The Barlow Committee has rightly stressed the mportance of attracting into the Government service a proper proportion of the ablest scientific workers produced by the universities of Britain. It is no less important, however, that the conditions of a scientific career, either within the Government service or without, should be such as to attract a fitting proportion of the ablest and most promising young minds among those who year by year enter the universities. That is the real reason for insisting on parity so far as possible between the administrative and scientific sides, and for reducing still further the difference in the prospects of the outstanding man who enters on an administrative as compared with a scientific career. If at the same time, as has been suggested, the general history of science and scientific method were made a compulsory examination subject for the higher Civil Service posts, and on their side scientific workers themselves saw to it that other cultural subjects were not neglected in the curriculum for a science degree, there is every reason to believe that under the Interdepartmental Scientific Panel the new proposals may provide the scientific worker in Government service not merely with improved conditions of remuneration, but also with a status and a freedom which will be a stimulus to creative effort and form the basis of an attractive and distinguished service.

ARISTOTLE'S CRITICISM OF PLATONISM

Aristotle's Criticism of Plato and the Academy
By Harold Cherniss. Vol. 1. Pp. xxvii+610. Baltimore, Md.: Johns Hopkins Press; London: Oxford University Press, 1944.) 33s. 6d. net.

MR. CHERNISS'S large volume will be most welcome to all serious students of Greek philosophy; none the less that it lays a heavy burden of duty upon them. There is already a vast literature in many languages dealing with the meaning and value of the criticisms of Plato by his most eminent pupil, and a wide discrepancy of opinion on almost every aspect of the problem. Often it is disputable whether a particular criticism is directed against Plato himself or against some Academic of the first generation, Speusippus, Xenocrates or another, and his version (or perversion) of the master's meaning. Where the *critique* is levelled against Plato by name, it is often uncertain what precise pronouncement of Plato is being attacked and what the precise point of the attack is meant to be. Even when Aristotle expressly quotes the words of a Platonic dialogue for controversial purposes, his quotations are often not quite accurate (presumably because the very format of a Greek book made 'verification of references' almost impossible). Even when the quotation is exact, we often see that its meaning has been twisted by Aristotle's habit of treating metaphorical language as though it were meant for a literal statement of matter of fact, or his tendency to assume that a word has in Plato the same precise sense as it bears in his own technical vocabulary. How, then, are we to deal with criticisms which, like most of those aimed in the "Metaphysics" at the "Theory of Ideas", are concerned with statements never expressly made in the Platonic dialogues at all? If Plato said these things, it must have been in what Aristotle calls his 'unpublished' teaching. How can we trust implicitly either Aristotle's apprehension of Plato's meaning, or even his accuracy in reporting Plato's words? Small wonder that there should be in the literature to which such a problem has given rise *quot homines, tot sententiæ.*

In the work of which the present large volume is the first half, Mr. Cherniss proposes to discuss this vast problem on a scale so far unprecedented, at least in the English language. He is in many ways well equipped for the task. His earlier volume on Aristotle's criticisms of the "Presocialists" revealed him as an excellent scholar, and he seems, moreover, to have made himself acquainted with almost everything which had been previously published on his present subject down to the present day in a way which can only awaken admiration and envy. Whether his own conclusions come in the end to be generally accepted or not—and I conceive that he himself would readily admit that on many points the last word has by no means been said—his book will remain an indispensable storehouse of learning and acute criticism from which future investigation will have to start, whether it ends by confirming his verdicts or not. Even those contemporary students whose views he is most concerned to overthrow will be sincerely thankful to him for his achievement, though they may not always feel themselves 'killed dead' by his great guns.

Properly speaking, it would be premature to attempt any 'review' of the book until Vol. 2 is before us. Only there does the writer intend to deal with the most difficult part of the whole subject, the alleged identification by Plato of his "Ideas" with *numbers* of some kind. In the present volume, he confines himself to acute examination of the strictures passed in the Aristotelian *corpus* on the 'ideal theory' in what Aristotle calls its 'original form' (except in so far as some of the appendixes are concerned more immediately with certain fundamental cosmological issues, particularly with the question whether Aristotle gives any support to the view that Plato at any time disputed either the motionlessness of the earth or its central position in the universe).

In this position of affairs, it seems almost imperative to suspend one's judgment of Mr. Cherniss's work until its publication is complete. From the present instalment, indeed, one may make a wide guess at what is to come, but only a *wide* guess. It is clear that, as is only natural, the writer attaches very great weight to the views of his eminent American predecessor as a Platonic scholar, the late Prof. Paul Shorey, on the life-long 'unity of Plato's thought'. I hope, however, that when he comes to discuss the so-called 'Idea-Numbers', he will handle the theme with less contemptuous impatience than Shorey, who brushes the whole subject aside as a mass of "clotted nonsense". The influence of Shorey's well-known "Unity of Plato's Thought", which is so manifest in the present volume, seems to me to be in the main beneficial. But I sincerely trust that in the sequel yet to come the unity will not be exaggerated, as I think it was by Shorey himself, into something like monotony. A great philosopher can be consistent through a lifetime without merely repeating himself endlessly.

If I occasionally find Shorey's influence unduly strong in certain places in the present volume, it is rather in some of the appendixes than in the main text. Mr. Cherniss is manifestly very anxious to convince himself that, as Shorey also held, Plato adheres from first to last to a cosmology with a stationary earth at the centre of the universe. Now it is certainly possible to make out a case for this view, a case which requires serious consideration, and Mr. Cherniss is fully entitled to do so. But there is also a case for disputing it. *Prima facie*, for example, the "Timæus" appears to ascribe motion of some kind to the earth, and Aristotle says in explicit words that the "Timæus" does this. It is undeniable that Theophrastus somewhere made a statement that appears to represent the aged Plato as having recanted his earlier belief in the earth's central position. This evidence has to be fairly and squarely met, and Mr. Cherniss sets himself to meet it. But I doubt whether he himself would claim that he has done so very convincingly. He argues ingeniously enough that in the passage of the "de Caelo" which has always been understood to assert that the "Timæus" teaches the mobility of the earth, Aristotle is only reporting an interpretation of that dialogue by certain unnamed Academics, which he himself regards as a misinterpretation. The evidence about a change in Plato's view as to the central position of the earth is disposed of by the suggestion that Plutarch, on whom we depend for our knowledge of what Theophrastus said, has misunderstood his author. All this, to be sure, is not impossible, but it is another question whether a judge who came to the consideration of the evidence with a mind not already as good as made up would find it very probable. (To me, I own, it seems a case of 'special pleading', but I too, of course, have my own initial bias.) I admit, indeed, that against those who have tried to find 'Copernicanism' in Plato Mr. Cherniss proves his case once for all.

I trust I have said enough to make it clear that though Mr. Cherniss's work cannot properly be reviewed to much purpose until it is completed, it is one of capital importance and will be indispensable in future to all serious students of Plato; and, indeed, of Greek philosophy generally. Unfortunately, the use which such students can at present make of Vol. 1 is seriously hampered by the absence of an index. This will, no doubt, be supplied in Vol. 2, and one hopes on the generous scale which such a book deserves.

A. E. TAYLOR.

ADVANCED MATHEMATICS

(1) Théorie des fonctions

Par Prof. Georges Valiron. (Cours d'analyse math matique, 1.) Pp. vi+522. (Paris: Masson et Ci 1942.) n.p.

(2) Les coniques

Par Prof. Henri Lebesgue. Pp. vii+190. (Pari Libr. Gauthier-Villars, 1942.) 150 francs.

THE two books under notice, published whi communications between France and Englan were cut off, have only recently reached Great Britai

(1) This, the first part of the latest course mathematical analysis, is an excellent book. In volume of 522 pages the author deals thorough with functions of both real and complex variable After proving a standard theorem, he usually appli it to an example of great intrinsic importance, ofte one prominent in recent research. This gives delightful freshness to the treatment. By the aid numerous historical notes, the reader learns how a idea first arose, and how it developed. For exampl in explaining the idea of an integral, we have reference to the early work of Cauchy and Lejeun Dirichlet, a full account of that of Riemann, a litt on that of Stieltjes, and then a whole chapter on th Lebesgue integral. Finally, we are shown the necessity of a further generalization, such as that due t Denjoy, and told where it can be studied.

To make room for the considerable amount matter not usually found in such courses, the autho has omitted elementary work likely to be well know to his readers, and has used rather small prin Unlike many recent English writers, he has include a chapter on elliptic functions. There are also sections on vector analysis, Riemann's zeta functio numerical integration, and many other subjec which, although there is no index, can be traced fro a very full table of contents. The second volume wi deal with functional equations.

(2) The name of Lebesgue is so well known in connexion with his theory of integration that we may b unaware that his primary interest was in geometr At various times he wrote several papers on conic Shortly before his death, he collected ten of thes together to form the five chapters of the present boo He intended to write an introduction to each chapte but was not able to complete more than the first tw

It is said that Prof. Lebesgue never read a mathematical paper through to the end, but always turne away to develop the subject on his own lines. H wished the readers of his own book to do likewis and to work out for themselves any of the numerou stimulating suggestions that he provided. This make it comparatively unimportant that the author w unable to give a final revision to his work, and impart greater unity to its somewhat miscellaneou contents. The first chapter gives suggestions f replacing the usual treatment of conics by ne methods, chiefly concerned with homographic tran formations of the plane. The second and third de with focal lines and focal circles. The fourth chapt is devoted to Poncelet's polygons, making conside able use of the work of Cayley and Sylvester. The fif chapter is an unusual treatment of diameters of pla algebraic curves, using the theory of finite groups.

The colloquial and sometimes ironical style of so of the pages may surprise the reader, but, accordi to the preface by his friend, M. Paul Montel, the recall the author's characteristic and attract lectures.

H. T. H. PIAGGIO.

A PHYSICAL THEORY OF THE SOLAR CORONA

URING the recent visit of several distinguished Indian men of science to Great Britain, the Phy- ical Society prevailed upon some of their number o deliver addresses to English audiences on subjects f their own choosing. On November 23, 1944, Prof. L N. Saha described to a crowded audience in the ooms of the Royal Society his theory of excitation n the solar corona. An abridged account of the ecture and the discussion which followed it has lready appeared[1], and the full text is now published y the Physical Society[2].

Prof. Saha believes that many outstanding phe- omena observed on the sun, such as prominences, pots and chromospheric flares, can best be explained y assuming that nuclear reactions take place all ver the solar surface, and especially vigorously in ertain limited parts. Nuclear processes in the deep nterior were first invoked some years ago to account or the sun's energy generation; but Saha now sug- ests that similar reactions occur on a reduced scale t or near the surface. He bases his opinion on two ets of facts, both of which, he believes, point to this onclusion. First, the occurrence of He I and He II ines in the spectrum of the chromosphere is com- letely inexplicable on present theories. The ordinary hermal ionization theory (itself Saha's work) is uccessful enough in explaining ordinary Fraunhofer ines of excitation potential of order 5 eV., but fails o account for such lines as He II 4686 A., a prominent ow-level line of excitation nearly 75 eV. observed in he flash spectrum. Secondly, Edlén's brilliant dentification[3] of the coronium lines, which calls for he existence in the outer atmosphere of the sun of on atoms which have lost 9–13 electrons, nickel toms which have lost 11–15 electrons, and calcium toms which have lost 11–12 electrons, requires a oronal excitation of the order of 500 eV., and vidently necessitates drastic revision of our ideas f solar physics. Saha provides this revision and claims o resolve both difficulties simultaneously in his new heory.

No particular nuclear reaction need be postulated o account for the helium super-excitation in the hromosphere: any one of the many nuclear pro- esses producing α-particles is sufficient. These articles (which are, of course, unobservable on the un) are supposed by Saha to be shot out at high peed from some sub-surface reaction, and projected hrough the reversing layer and chromosphere. There hey will ionize solar atoms along their path by ollision, losing energy the while until each can retain captured electron, so forming ionized helium, and ventually another to give neutral helium. Those articles which capture electrons in excited states ill be in a condition to emit the spectra of He II nd He I respectively, which will thus be expected s indeed they are observed) in the low and high hromosphere respectively. The presence of the line D_3 (He I, 5876 A.) in absorption above disturbed reas of the solar surface suggests the presence of a emporary helium-rich atmosphere above spots which ay result from these nuclear reactions.

A more specific mechanism is postulated by Saha account for the super-excitation in the corona. He supposes that in the reversing layer, below the ase of the chromosphere, a nuclear process takes lace which is identical with or closely akin to that of uranium fission. The products are high-energy stripped atoms which are shot through the solar atmosphere, ionizing solar atoms by collision in its lower parts, and capturing electrons and emitting X-rays and forbidden coronal radiation farther out.

Among the debris produced by their passage are electrons—δ-rays which are knocked forward and escape, to constitute the electron atmosphere which we know as the outer corona. The reaction produced in the laboratory by neutron bombardment of uranium or thorium is of the type

$${}_{92}U^{235} + {}_0n^1 = xA^{M_1} + yB^{M_2} + Z_0n^1 + Q,$$

where A and B are new nuclei of masses M_1 and M_2 and charges x and y; Z is the number of neutrons (usually three or four) evaporated: and Q ($\sim$ 200 MeV.) is the energy released. In binary fission of this type, A and B are usually unstable and pass by a chain of β-ray emissions to stable end-products. The energy Q is distributed between these according to the law of conservation of momentum; and the important point is that it is so high that the fission particles separate with velocities much larger than the orbital velocities not only of their outer electrons but also of many of those in the inner shells. As a result, the fragments start their independent career highly ionized and moving at speeds of the order of the orbital speeds of electrons in the inner orbits of atoms. Saha shows that if the initial process is a ternary or quaternary fission, the fragments, after stabilization through β-emission, are likely to be atoms from calcium to nickel emitted with a kinetic energy of about 60 MeV. For an iron atom this means that the outer 15 electrons cannot be retained, and the fragment starts out with the ground structure $1s^2 2s^2 2p^6 3s$. Saha calculates the range of particles of this kind in a solar atmosphere of plausible constitution, and decides that only such fissions as occur at or above the reversing layer can contribute to the coronal radiation: those which occur deeper in the sun give particles which are stopped by collision before they penetrate the chromosphere.

The subsequent history of the stripped atoms is as follows. The Fe^{+15} ion (itself spectroscopically unobservable) loses energy by collision with solar atoms along its trajectory and eventually captures an electron, bound or free, to become Fe^{+14} in an excited ($3s\,nx$) or normal ($3s^2$) state. In the former case it emits the extreme ultra-violet spectrum of Fe XV before reaching the ground-state. There are no metastable levels, so no visible radiation is to be expected. Then the process of electron capture is repeated and the Fe^{+13} ion is formed. Allowed transitions here can again give rise only to radiation of extremely short wave-length, but this time the ground-state is an inverted doublet, and the forbidden transition ${}^2P_{1/2} - {}^2P_{3/2}$ results in the emission of the famous green coronal line of Fe XIV. Successive electron captures gradually build up the next electron shell, and the spectra Fe XIII . . . Fe IX are emitted. Most of these contain forbidden lines in the accessible region, and most of the observable lines in the corona are attributed by Edlén to such of these ions as have metastable ground-levels, or to their isoelectronic analogues in nickel or somewhat similar calcium ions.

The theory thus depends upon the occurrence of ternary, quaternary or possibly unsymmetrical binary fissions in uranium or thorium near the sun's surface. Uranium has not yet been detected spectroscopically in the reversing layer; but faint lines attributed to ionized thorium have recently[4] been discovered in the Fraunhofer spectrum. Presumably no great abundance of fission nuclei is necessary, since the coronal radiation is, after all, very weak relative to the thermal radiation of the whole sun; it can be observed only during total eclipses or by taking extraordinary precautions against extraneous light at other times. A more difficult point concerns the apparent selection of iron, nickel and calcium as fission products. Why should no lines of, say, highly ionized cobalt, manganese, copper or potassium appear? This is partly a spectroscopic matter: the elements found are better suited for identification than all the others except cobalt, and here, as elsewhere, absence of the spectrum of an element is no guarantee of the absence of the element. A faint coronal line at 4359 A. is indeed attributed to Co XV. But there is no denying that the iron, nickel and calcium lines represent most of the coronal emission, and the contiguous elements, even if they turn out to be represented among the fainter lines, are likely to be relatively rare. Saha attributes this to the greater probability that fissions will result in even atomic numbers than in odd, the former having many more stable isotopes than the latter. This leaves some doubt concerning chromium and titanium (especially the former, which has predicted forbidden lines in the accessible region), and an alternative explanation put forward by Edlén in his original paper[5] deserves consideration. He noted there that the observed lines belong to elements common in meteorites, the implication being that coronal matter is not directly of solar origin at all, but is a cloud of meteoritic gas collapsing on to the solar surface. Saha will have none of this on energetic grounds, however, and points out that the velocities involved (622 km./sec. from infinity to the solar surface, less to the corona) are not sufficient to produce the observed ionization.

The fate of Saha's stripped atoms, once they have emitted the coronal lines, is doubtful, for it depends on the ranges of the various particles in a part of the solar atmosphere where the composition is as yet rather uncertain. It might be supposed that the process of electron capture outlined above would go on as the ion continued its progress through the corona, and that accordingly lines due to Fe VIII, Fe VII . . . Fe I and the corresponding nickel and calcium lines should be emitted at greater heights. But between Fe VIII and Fe III the capture is in *d*-orbits, where the capture cross-section is small, so that even where other conditions (for example, presence of deep metastable levels with accessible transitions) are favourable, the lines will be expected to be faint. In fact, the probability of electron capture may be so small that these less highly ionized particles may escape into regions devoid of hydrogen atoms or electrons before they can make further captures. The lower ions will in that event play no part in coronal emission, though they may become of interest to geophysicists!

The value of the new theory, if it can be supported at the many points where observational verification is possible, lies not only in the explanation it affords for the observed high excitation in the inner part of the corona, but also in the light it throws on the spectrum of, and intensity distribution in, its outer parts. That it suggests that the outer corona is not in equilibrium but consists of outward streaming δ-rays continually ejected from solar atoms by fission fragments is an advantage; for questions concerning the origin, maintenance and stability of the out corona have hitherto been embarrassments to tho who held it to be an atmosphere in equilibriu Saha's conception of the chromosphere and inn corona as a sort of gigantic cloud chamber, whe the tracks of individual particles are invisible b where the particles are so abundant that their recombination spectra are observable, is more than picturesque illustration. It removes the difficulty accounting for the extremely high 'temperatur needed to produce the coronal lines. It was alwa incredible that temperatures of millions of degre could exist in parts of the solar atmosphere where black sphere would be expected to reach at mo 4,500° C. It is now clear, if Saha is right, that th phenomenon is quite local, and is comparable wit the local luminescence produced in our own atm sphere by meteors. (Perhaps a better comparison, view of the direction of motion of the particles, with terrestrial rockets.)

Many points remain to be cleared up, of cours and much experimental and theoretical work mu be done before the theory can be regarded as mo than tentative. But as a first attempt to accou for the extraordinary features of the solar coro brought to light by the identification of the emissio lines in its spectrum, this theory merits and w receive astrophysicists' serious consideration.

THE CITY AND GUILDS COLLEG

ENGINEERING AT THE IMPERIAL COLLEGE

By PROF. E. F. D. WITCHELL

THE City and Guilds College forms the engineerin section of the Imperial College of Science an Technology, the centenary of which was recentl celebrated (see *Nature*, Nov. 3, p. 518 *et seq.*). As i name implies, the City and Guilds College itself ow its existence to the City Livery companies, who m at the Mansion House on July 3, 1876, under th presidency of the then Lord Mayor and decided t devote attention "to the promotion of educatio throughout the country and especially to technic education". As a result of this meeting, the Cit and Guilds of London Institute for the Advanceme of Technical Education was established in 1878 an was incorporated in 1880. The provisional committe of the Institute recommended "that the objec which the Guilds had in view would be best attaine firstly, by the establishment of a Central Institutio or College for the advanced education of those wh had already acquired sufficient knowledge of scien or the arts to profit by instruction in the industri application of these; secondly, by conducting exan inations in technological subjects; and, thirdly, b the establishment of local schools for artisans an workmen, and by co-operating with and otherwi assisting local effort, more especially, but not e clusively, within the Metropolis".

The first of these recommendations led to t establishment of the College in Exhibition Road. T foundation stone of the building was laid in 1881 the Prince of Wales, who opened the new building three years later.

The College was known as the Central Institution, nd its declared objects were "to afford practical, scientific and artistic instruction which shall qualify persons to become: (I) technical teachers; (II) mechanical, civil and electrical engineers, architects, builders and decorative artists; (III) principals, superintendents and managers of chemical and other manufacturing works.

"The main purpose of the instruction to be given in this Institution will be to point out the application of the different branches of science to various manufacturing industries, and opportunities will be afforded or the prosecution of original research with the object of the more thorough training of the students and for the elucidation of the theory of industrial processes."

It was proposed to carry out these objects by instituting five departments, namely: (1) Chemical Technology; (2) Engineering; mechanical, civil and electrical; (3) General Manufactures; (4) Architecture and Building Construction; and (5) Applied Art.

Students were required to pass an entrance examination in mathematics, pure and applied; chemistry; physics; drawing and modern languages. The courses in all departments were to be of three years duration, and the diploma of the College (A.C.G.I.) was to be awarded to those who had studied satisfactorily during the course and passed the various examinations with credit.

Three professors were appointed in April 1884, namely: Henry Edward Armstrong, as professor of hemistry; William Cawthorne Unwin, professor of ngineering; and Olaus Henrici, professor of mechanics and mathematics. Later in the year, William Edward Ayrton was appointed professor of physics. These four professors were charged with devising the schemes of education which should be adopted for training students following diploma and special ourses in the various departments. The general scheme proposed for diploma students provided that the first-year course should be a common course for ll students no matter in which department the student wished to graduate. The subjects studied were mathematics, chemistry, physics, engineering drawing and engineering workshop practice. In the second year a small amount of divergence from the common course was permitted, especially for students in chemistry; but for engineering students almost all the course in electrical, civil and mechanical engineering was substantially the same. In the third year the student spent the whole time in the department f his choice, with the exception that during the winter term one day per week had to be devoted to study in another department. Mathematics was studied by all students throughout the three years f the course.

It will be seen that the scheme recognized the nportance of making a fairly wide training in general and applied science the basis for a satisfactory course in technological studies, and it deliberately discouraged too early specialization in any one branch of learning.

Evidence that the course as devised was sound in principle is provided by the fact that the alterations in the scheme during the last sixty years have been comparatively few. Perhaps even more convincing the testimony of past students, who affirm how useful in their professional careers they have found the general training received in the College.

The original proposals of the City and Guilds of London Institute envisaged giving instruction in general manufactures, architecture and building and applied art, as well as in chemistry, technology and engineering. A School of Art Wood Carving was instituted and lectures were given in architectural and allied subjects; but it soon became evident that the College buildings, although judged to be large and capacious by the standard of those days, could not adequately house classes in all the intended subjects. In 1887 Prof. Ayrton estimated that the new College was providing for little more than half the work for which it was originally intended, and only two years later Prof. Unwin reported that experience indicated that the resources of the Institution, both as to staff and apparatus, would be considerably taxed by the two hundred students for which the building was designed.

In 1893 the name of the College was changed from the "Central Institution" to the "Central Technical College". Under this name the College continued to function until it became part of the Imperial College in 1910, when it was renamed the "City and Guilds (Engineering) College", and eventually the "City and Guilds College". The style under which it was known during the first twenty-five years of its existence is still retained in "Old Centralians", the name of the Association of past students of the College.

By 1893 the number of students following the courses in engineering and chemistry exceeded two hundred, and it seemed obvious that the whole of the accommodation in the College would be required for the proper teaching of these subjects. In 1897 the School of Art Wood Carving was transferred to the Imperial Institute, and the rooms which it had occupied were used for a laboratory for mathematics and mechanics. The basement of the Royal School of Art Needlework, which was built in 1901 on the site immediately south of the College, afforded much-needed accommodation for the Electrical Machines Laboratories, which had previously been inadequately housed; and the transference of the Electrical Laboratories in turn enabled an extension of the Civil and Mechanical Engineering Laboratories.

In 1900 the 'internal' side of the University of London was established and the College became a School of the University in the Faculty of Engineering.

The chief event in the College history since that date has been its incorporation with the Royal College of Science and the Royal School of Mines to form the Imperial College of Science and Technology. The immediate effects of the amalgamation occurred in 1913, and were the closing of the Chemical Department, the fusion of the Mathematical Departments of all three Colleges into one department, and the division of the Civil and Mechanical Engineering Department into Departments of Mechanical Engineering and Civil Engineering. Further facilities for research were provided, and the size of the College was approximately doubled by the building of engineering workshops in the rear of the building and the erection of the Goldsmiths Extension on the land immediately to the north of the original building. Most of the design of the general lay-out of these extensive laboratories is due to Prof. W. E. Dalby, who had succeeded Prof. Unwin as University professor of engineering in 1904. The foundation stone of the Goldsmiths Extension was laid in 1909 by King Edward VII and the building was finished in 1914. Owing to the War, the official opening of the building was postponed until 1926, when the ceremony was performed by the present King, then Duke of York. A much later addition to the College was the transference of the Aeronautical Department from the Royal College of Science, and still more recently the formation of a Department in Chemical Engineering.

The increase in the number of students has more than kept pace with the increase in accommodation. As mentioned above, the College was originally designed to accommodate two hundred students. This figure was exceeded in 1893 and kept steadily rising until, in 1911, it reached a total of 589 registered students, of whom 430 were working full time.

From the beginning, the teaching given in the College was fashioned on an experimental approach to knowledge rather than on precept. Lecture courses were, of course, given in all the subjects selected for study, but in all departments the importance of experimental work performed by the student was emphasized and the need for accuracy in such work was stressed. This point is well illustrated by extracts from the programme of the Central Institution for the session 1892–93. In the course of instruction in the Department of Mechanics and Mathematics, we read: "In the laboratory the experiments are performed by the students themselves. The experiments are all quantitative; that is to say, in each experiment the student has to make some definite measurement . . ."

Again, it is stated of the Department of Physics and Electrical Engineering: "The instruction is given largely by tuition in the laboratories, the lectures being rather for the purpose of aiding the students in their laboratory practice than of forming a distinct course by themselves". In the Chemical Department the object of the general first-year course is thus described: "The object aimed at in this part of the course will be to encourage habits of accuracy and thoughtfulness and to teach the art of experimenting with a logical purpose rather than to impress mere facts".

In the experimental sciences instruction by inquiry and experiment must always be slower than that given by lectures, but there can be little doubt which method is the better from an educational point of view. Training in careful habits of thought and logical deduction is an important part of any system of education, and the student is more likely to learn these by the success or failure of his own experimental work than by listening to lectures, however clear or eloquent they may be.

Experimental work also teaches the student that accuracy in observation and performance is needful for success. He learns the degree of accuracy which can reasonably be expected in such work and, what is perhaps quite as important, the limit of that accuracy. For this reason laboratory work has always occupied an important place in the College curriculum, and there has been insistence upon the writing of careful and complete records of the work.

It is difficult to assess the influence which the College has exerted on the practice and profession of engineering. It would, however, be easy to compile an impressive list of past students who have taken and are taking a leading part in the profession both in Great Britain and abroad, and who acknowledge the benefit to themselves of the training they received. They are to be found in all branches of engineering, administrative, executive, commercial and professional. Most graduates naturally practice in that part of the profession in which they were trained, but many who were trained in one branch now occupy responsible positions in some other branch. Thus men trained in mechanical engineering are to be found as wireless broadcasting engineers, electrical graduates are in charge of mechanical plant and so forth. The facility with which th men pass from one branch of engineering to another and seem to acquit themselves worthily in each, is tribute to the soundness of the College tradition o insisting on a training in general engineering befor allowing specialization in any one branch.

It must be remembered that, when the Colleg was founded, technical education was only just beginning, and the students passing from the College in the early days had the responsibility of proving to the profession that technical training was really worth while; to-day the need for such training i taken for granted and every town of reasonable size has some sort of technical institute. Even thirty-five years ago the students often found it wise when seeking employment with an engineering firm to conceal the fact that they were university graduates now, a degree is becoming a *sine qua non* for employment.

It would be extravagant to claim that the College is responsible for this change in the general outlook in Britain of the engineering profession, but it can be justly claimed that it has contributed largely to this more satisfactory state of affairs.

THE UNITY OF SCIENCE

On October 20 a meeting of the Association of Scientific Workers was held at Gas Industry House, S.W.1, "to explore the inter-relations between the natural and social sciences". The chair was taken by Sir Robert Watson-Watt, and the chief speakers were Prof. J. D. Bernal, Mrs. J. Robinson and Mr. Dennis Chapman. In his opening remarks, the chairman explained that the meeting had been convened to examine the implications of the increasingly closer relations which were growing between workers in the natural and social fields of science He therefore stressed the indivisibility of science in furthering what he called the "engineering efficiency" of the community. He announced that the Lord President of the Council, the President of the Board of Trade, and the Minister of Supply and Aircraft Production had been invited to attend the meeting, and all three Ministers had expressed their keen interest in the matter under consideration. The Lord President had replied that he would consider sympathetically any proposals formulated at the meeting which would be conveyed to him; the Minister of Supply and Aircraft Production was represented at the meeting by one of his directors of scientific research.

Prof. J. D. Bernal distinguished two aspects of the principle of the indivisibility of science. The phrase might be used in the philosophical sense of the unity of all knowledge, or in the highly practical sense of employing all the resources of scientific method regardless of the material to which it was applied. By establishing this principle in the practical sense, the artificial barriers hitherto separating 'natural' and 'social' scientists would be broken down. Prof. Bernal remarked that the demarcation between the natural and social sciences was of relatively recent origin; in seventeenth-century England, when odern science began to flourish, this line of distinc- on was not drawn, and indeed, some of the most ninent of the early fellows of the Royal Society ere those who had distinguished themselves in what ould now be called the social sciences.

He went on to say that there had for long been a istinction between the observational and the perimental sciences; but this was breaking down as direct result of the growing use of statistical method. tatistical methodology had come to mean designing periments in any field in such a way as to yield the aximum information, and not merely providing ays of analysing data. The natural and social iences were being brought together in a twofold anner: first, by a common statistical technique; cond, by a common area of operation. The inte- ration of the problems and methods of the natural nd social sciences was well illustrated by the war- me need to ascertain the effects of air-raids on roduction. Here the task was not merely to discover e number and physical effects of bombs but also assess the dislocation to the life of an industrial ommunity, and this involved the study of human ehaviour, including its economic aspects.

We were now experiencing a transition to a con- rolled and consciously integrated human life. Hence he great need for social experiments, designed to rovide the information whereby their outcome ould be evaluated with precision. Prof. Bernal elieved also that we were witnessing a revolution the methods of government, and this had a direct earing on the use of science. The problems of a com- unity that the man of science might be called upon o solve were as much 'social' as 'natural'. The object f the meeting was to facilitate in practice, as well as theory, the integration of the two groups of sciences. One of Prof. Bernal's specific proposals was that the ssociation of Scientific Workers should consider imulating broad surveys of the national economy in lation to its transformation from war to peace.

Mrs. Robinson, speaking as an economist, gave a arning to those who expect to get definitive and onclusive answers to economic questions. Problems f economics and allied studies were, she thought, ecessarily 'grubby' as compared with the neat and lear-cut problems of physical science. Hence it was uitless to pursue a perfectionist aim. Moreover, ectional economic problems could not be solved in olation from the economic setting of the community a whole. It was of no use declaring, for example, at a machine would work more efficiently if it were ade of diamonds. Schemes had to be formulated nder the restriction of their possible application in dustry. Mrs. Robinson said that a start had been ade in merging the efforts of various scientific orkers in studying coal production, housing and wn-planning. As illustrative problems which might attacked by composite working parties, she men- oned: (1) the analysis of accumulated medical atistics; (2) the interaction between health and nditions of living; (3) economic aspects of bac- riological control of milk; and (4) output per man ur in industry; why, for example, was industrial ficiency in the United States, as judged by output r man hour, reckoned to be twice that of the United ngdom?

Mr. D. Chapman deplored the loose way in which itish sociologists were organized. The Institute Sociology was, he thought, out of touch with alistic work in the field, and sociology in the uni- rsities tended to be associated with the arts or with social philosophy rather than with science. Sociology at the London School of Economics was, by virtue of its location, he thought, unduly dissociated from scientific work in other parts of the University of London. Sociological research was very costly, and in the absence of adequate funds, sociological inquiries in England had inevitably been descriptive, and qualitative rather than quantitative. In his view this tended to make them trivial in character. The strongest branches of the social sciences were educational, industrial and social psychology, where there was a tradition of experimental method.

He made it clear that a very great deal of administrative action had its scientific aspects, and there should thus be scientific study of the problems at issue. Thus there was a marked contrast between the success of the Directorate of Selection of Personnel at the War Office, due to the application of scientific method to selection, and the primitive methods employed by the Ministry of Labour in dealing with comparable problems. Mr. Chapman deprecated the limitation under which the War-time Social Survey had had to operate, being wholly engaged on problems, sometimes of a trivial nature, referred to it from outside. He directed attention to the fact that Government Departments like the Ministry of Works and the Ministry of Town and Country Planning had appointed scientific advisory bodies which did not include social scientists. Other departments, like the Ministry of Health, did not employ social scientists though there were many problems which could be adequately dealt with only by persons with training in that field. Finally, he suggested that some co-ordinating body should be set up as a Social Science Research Council.

In the discussion which followed, a wide range of problems came to light, the solution of which depended on the joint efforts of workers in both the natural and social sciences. Several instances were cited from the work of the Ministry of Fuel and Power. The future of the coal industry was threatened not only by a reduction in manpower but also by the inefficient utilization of coal. The efficiency of plant using coal probably turned as much on the care used by the plant operator as on any other factor. Yet little was known about ways of bringing about an increase in the care given by operatives. No serious study had been made of the causes of the success or failure or indifferent results of various bonus schemes. In this problem technical, social, and economic factors were closely interwoven. Similar considerations applied to the study of the optimal retail price of coal of different grades of quality from the point of view of fuel economy. Thus, the method of applying flat-rate increments was a strong financial inducement to use good quality coal that was in short supply.

As an illustration from a different field, attention was directed to the apparent conflict between the needs of health on one hand, and taste on the other, in controlling the quality of milk by inoculating dairy herds against tubercular infection. There was danger in over-emphasizing one aspect at the expense of the other. In this connexion a special plea was made for integrating sociological and psychological considerations in scientific planning, and for encouraging the social scientist to study the relative importance of economic, æsthetic, health and other values in various contexts. Furthermore, the problem of how to change values and inducements was, it was suggested, a legitimate subject for scientific study.

Many other problems were suggested for investigation by 'working parties' composed of men of science with diverse training. Various speakers made suggestions for increasing the effectiveness of working parties. One suggested the inclusion of a trade unionist; another suggested including an administrator. The Association of Scientific Workers had already set up one working party to study problems of fuel and power. Yet another suggestion was to the effect that a working party be appointed to investigate the factors which prevented the community as a whole from reaping the benefits of scientific effort; this was described by one speaker as an investigation into 'social pathology'.

A good deal of the discussion was devoted to the possibility of extending into civil life the kind of 'operational' research that had been so successful in the Services and supply departments. In the Air Ministry, for example, an 'operational' research team working with Telecommunications Research Establishment had been assigned the task of introducing radar devices at R.A.F. stations. In time the team grew into an advisory body which was consulted on a very wide range of tactical and strategical problems arising out of the use of operational equipment. Most of the crucial problems could only be studied adequately by the closest co-operation between workers with very diverse training, background and interests. The work required close and constant contact with executive officers of the R.A.F.

As regards securing Government sanction for the application of scientific discoveries, comment was made on the 'vertical' structure of British government administration, and the consequent difficulties in getting inter-departmental co-ordination to operate schemes of the TVA type.

Several speakers referred to the resistance encountered, at different political and administrative levels, to the application of science to the problems of the civilian community. In the Services, once the policy had been adopted, the hierarchical structure could be used to ensure the introduction of new techniques in a way which was scarcely to be hoped for in private industry.

It was unanimously agreed to set up a Joint Sciences Committee to consider the proposals formulated at the meeting.

EFFECTIVE AND INEFFECTIVE STRAINS OF LEGUME NODULE BACTERIA

By DR. H. G. THORNTON, F.R.S.
Soil Microbiology Department, Rothamsted Experimental Station, Harpenden, Herts

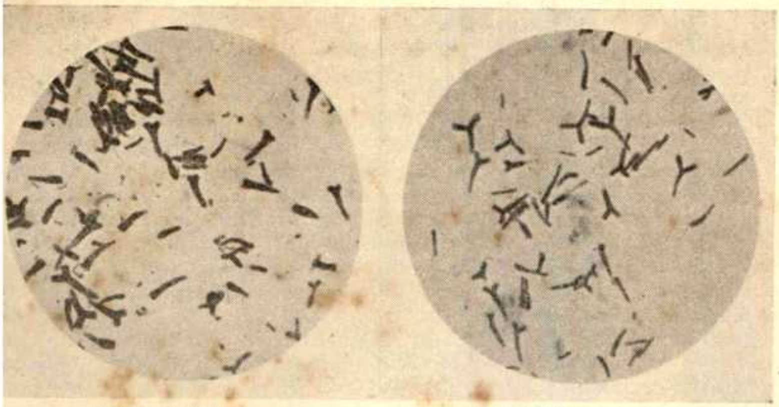
PROF. A. I. VIRTANEN, in a recent article in *Nature*[1], gave a brief summary of the work carried out in his laboratory on legume nodule bacteria. We await with interest the publication of these results in detailed form. It is already clear, however, that some of our investigations at Rothamsted have been on lines parallel to his, and that our results are complementary to some that he describes. A summary of our work where it touches on that at Helsinki may therefore be of interest.

Nature of the Ineffective Response

In observations on the structure of nodules produced by effective and ineffective nodules, Chen and Thornton[2] found that in ineffective nodules the h cells filled with bacteria were far fewer in numl than in effective nodules, and also that these ce and their contained bacteria disintegrated after period of active life which was but a small fracti of that possessed by those in effective nodules. the strains compared, the differences in volume a duration of this central 'bacterial' tissue were fou to account quantitatively for the difference nitrogen fixation, in that the quantity fixed per u volume of bacterial tissue in unit time was simi for the effective and ineffective strains. This res was obtained with strains both of clover and bean *Rhizobium*.

The transient nature of the 'bacterial tissue' ineffective nodules may explain two observati recorded by Virtanen in his article. First, the abse of red coloration in ineffective nodules may thus explained. Quantitative data are needed to relate amount of pigment with the degree of effectivene but we have examined nodules produced by seve hundred strains covering the whole range of effecti ness, and we confirm the observation that red col is rarely detectable in the centres of very ineffect nodules. But the red pigment is formed in the cent 'bacterial tissue,' so that the very short time dur which this tissue persists in ineffective nodules n well be insufficient to enable a visible amount of pigment to accumulate in them. Thus the abse of visible pigment may be the result of the ch acteristic behaviour of ineffective nodules and not cause; this absence cannot therefore be conside to prove that the pigment is necessary to nitro fixation in the nodule, though it may well be. T caution as to interpretation in no way detracts fr the great interest of the red pigment, or of its ide fication with hæmoglobin[3], or of Virtanen's obser tions on the change from red to green.

Secondly, Virtanen states that his ineffect nodules were found to contain bacteria in the stage. In nodules produced by all strains of *Rhizobi* that we have observed, the recently infected tis contains rod-shaped bacteria imbedded in the sli of the 'infection threads'. Similarly, in the integrated region of old nodules, such bateria remain are in the rod stage often imbedded in sli masses. In active effective nodules these rod-sha bacteria are not conspicuous because the region which they occur are small compared with the la volume of the central bacterial tissue, where bacteria within the cells of the host plant usually oc as swollen 'bacteroids'. But in ineffective nod this latter tissue has so short a life that in mos those observed at any one time it has either not formed or has already disintegrated; in both th conditions only rod-shaped bacteria are found. have observed, however, that the swollen 'bactero found during a short period in ineffective nodules in general similar in shape to those in effec nodules (see photomicrograph), though strain dif ences unrelated to effectiveness do occur[2]. It is t however, that the relation found by us of the quan of nitrogen fixed to the volume and duration of 'bacteroid'-containing tissue carries the implied s gestion that no detectable fixation occurs in th parts of the nodule where the bacteria are presen small rods, and is thus consistent with Virtan view. But in order to explain the behaviour of effective strains, it is necessary to discover why nodules produced by them fail to develop an adeq volume of the central tissue containing the swo



Strain *A* (effective) Strain 2027 (very ineffective)

BACTERIA FROM THE CENTRAL TISSUE OF CLOVER NODULES PRODUCED BY TWO STRAINS OF *Rhizobium*.

acteria or to maintain it from disintegration. This certainly the result of a maladaptation between the acteria and the plant, since individual plants can e found in which a normally effective strain of the acteria will behave ineffectively, and vice versa. It as found in this Department by P. S. Nutman npublished work) that *Trifolium pratense* possesses ecessive genes that produce a typical ineffective esponse with a normally effective strain of *Rhizobium*. ur results suggest that the ineffective response may e related to the induced production by the plant of ubstances inimical to the bacteria[4].

Changes in Effectiveness of Bacterial Strains

The abnormal responses given by plants possessing ertain genetical compositions do not produce any sting change in the bacteria. If these are re-isolated om such abnormal nodules and supplied to a normal lant, they will produce the degree of effectiveness pical of the original bacterial strain. It has been aimed by previous workers that continued passage rough the host legume will progressively alter the fectiveness of a bacterial strain. The negative esults of Virtanen's attempt to change the effectiveess of a strain in this way are in general agreement ith unpublished results obtained here, in which fective and ineffective strains of clover *Rhizobium* owed no progressive changes on lant passage, although they readily developed treme variants in effectiveness on culture in some erilized soils as well as under other laboratory onditions.

Infection by Mixed Strains of Nodule Bacteria

Investigations carried out at Rothamsted also have bearing on those of Virtanen relating to the succesve application to the host plant of two strains of *hizobium*. H. K. Chen[5] found that when different rains were supplied singly to the host plant, the umber of nodules per gram of root attained a limit at was specific to each bacterial strain, though the enetical analysis referred to above has shown that enes in the host plant *Trifolium* also control the umber of nodules formed.

As a consequence of this limit, the nodule-producing apacity of a root system can become so saturated at no more nodules will result from a further supply f bacteria whether of the original or of a different rain of *Rhizobium*[6]. This condition readily obtains ith peas and soy beans grown in pots, where the root system makes most of its growth in the first few weeks. In clover, the root system of which continues to grow during a long period, the nodules first formed did not inhibit further nodule formation by the same or by a different strain. No evidence could be found of specific immunization by the nodules of one strain against the entry of a different strain.

When two strains were simultaneously supplied in initially equal numbers to pot-grown peas, acute competition in the root surroundings resulted in the preponderance of one of the strains both outside the roots and in the plant. In similar experiments with clover, one pair of strains showed this selective competition; but with another pair, neither strain showed a selective advantage, the percentage of nodules produced by each strain being in proportion to the relative number produced respectively by the strains in pure culture.

The factors controlling competition between strains of *Rhizobium* in soil as well as those that limit the number of nodules produced afford interesting problems that are now under investigation.

OBITUARIES

Prof. E. J. Williams, F.R.S.

THE death at the early age of forty-two of Evan James Williams, professor of physics at the University College of Wales, Aberystwyth, has taken from us one of the most brilliant physicists of our generation. When finally compelled by his fatal illness to give up his work at the Admiralty, Williams returned to the village of Llanwenog, near Llanybyther, in the heart of rural Wales, near the border of Cardiganshire and Carmarthenshire, where he and two brothers were born, and where his mother and his father, a master stonemason, still live.

Educated at Llanwenog National School and then at Llandyssul County School, as was his elder brother, now Dr. D. Williams, of the Aeronautical Structural Department of the Royal Aircraft Establishment, Farnborough, E. J. Williams quickly showed his brilliant qualities of mind. At the age of sixteen, by chance noticing in the local paper that some scholarships were open to competitive examination on the following day at Swansea, but finding the last train gone, Williams made the fifty-mile journey by pillion on his brother's motor-cycle, and won a £60 scholarship, and so began his academic career. From University College, Swansea, he went to Manchester to work under W. L. Bragg, then to Cambridge to work under Rutherford. After a year in Copenhagen with Niels Bohr, he returned to Manchester, and then went on to Chadwick at Liverpool. In 1938, he was elected to the chair of physics at Aberystwyth. In 1939, at the age of thirty-six, Williams was elected into the fellowship of the Royal Society.

Williams was distinguished both as an experimental and theoretical physicist. His experimental work was mainly concerned with studies of electronic and atomic collision processes, using the cloud chamber of C. T. R. Wilson. The most striking of his experimental achievements was the direct demonstration in 1940 by the cloud chamber method of the decay of a cosmic ray meson into an electron.

Skilful though he was as an experimenter, Williams' distinction lay perhaps even more in his rare gift of analysing in detail the mechanisms of complicated physical processes, using a minimum of mathematical analysis and a maximum of physical understanding. In this quality of mind he had something in common with Niels Bohr, in whose institute in Copenhagen Williams did some of his best work. In a series of papers on collision processes, chiefly in the *Proceedings of the Royal Society*, and particularly in a brilliant but little-known paper, "Correlation of Certain Collision Problems with Radiation Theory", published in Denmark in 1935, Williams showed these rare powers to the full. The development of what is now generally known as the Williams-Weiszäcker method of impact parameters, for the approximate treatment of atomic collision problems, has the valuable quality of revealing the underlying physical mechanisms, which are often obscured by the heavy mathematical machinery of more rigorous methods. A particularly fertile application of these ideas was made by Williams to predict the later verified logarithmic rise of ionization with the energy of a very fast particle. As applied to the simpler collision processes, the impact parameter method was at first sometimes thought of as only giving an approximate answer and a visualizable picture of what could be calculated exactly by orthodox quantum mechanical methods. However, in recent years it is coming to be more and more used in solving the very complicated problems of the collision of fast neutrons, protons and mesons; this is so just because the complexities of the problems have made solution by more rigorous methods either very difficult or nearly impossible.

During the War, Williams turned his powerful analytic mind to many of the most important problems of the U-boat war, and made contributions of decisive importance to the winning of the campaign. His first work in this field, made during the summer of 1941, lay in the analysis of the process of attack on U-boats by aircraft. Simple but penetrating arguments, based on the actual observed facts of such attacks and on theoretical reasoning about these facts, showed that certain changes in the depth-setting and spacing of the depth charges should lead to a striking improvement in the number of U-boats sunk. The changes were made and the predicted results were attained, thus revolutionizing the attacking power of Coastal Command aircraft.

During 1942 Williams, who was then head of the Operational Research Section of Coastal Command, studied in great detail the tactics of harassing the U-boats by aircraft during their passage through the Bay of Biscay on their way from their bases to their hunting grounds. It was largely due to Williams' keen analysis and powerful advocacy that an augmented and improved 'Bay Offensive' was staged in early 1943. The results, in terms of U-boats sunk, were not only in startling agreement with his predictions, but also were one of the important facto
that led to the defeat of the U-boat campaign in t
summer of 1943, and so made possible the seriou
planning of the invasion of Europe.

Part of the story of the technical battle of wits-
particularly in the field of radar—the victory
which made this 'Bay Offensive' successful, h
already been told. The tactical battle of wits, wage
by Coastal Command and the Admiralty staffs again
the U-boat command, were analysed with great insig
by Williams, working in close collaboration with t
Naval and Air Anti-U-boat Staffs. Some day, perhap
it may be possible to tell much more of this fascinati
story.

During the last months of his illness, when Willia
took up again his favourite subject of the quantu
theory of atomic collision processes, he confess
that he still found the subtle intricacies of the U-bo
war of comparable intellectual interest.

Scientific men of all lands will mourn the loss
this brilliant young Welshman. His death, coming
soon after that of R. H. Fowler, means a sad weake
ing of the none too wide ranks of British theoreti
physicists. P. M. S. BLACKETT.

Prof. Marc Tiffeneau

MARC TIFFENEAU was born at Mouy on Novemb
5, 1873. After leaving school he was apprenticed
a druggist in Sainte-Maxence for a year, after whi
he went to Paris, where he continued his training f
two years longer. Then he studied at the Éco
supérieure de Pharmacie, where at the same time
his friends Valeur and Blaise he came under t
influence of Béhal. After an academic career
exceptional brilliance, he acted for five years as
demonstrator in the department. By this time
had qualified as a pharmacist, and in this capacit
was attached for many years first to the Hôpit
Boucicaut and later to the Hôtel Dieu. In bot
those hospitals he had the good fortune to find amp
facilities for research, of which he took full advanta
for in due course he shared his enthusiasm for che
istry with a large band of ardent workers, amo
whom Orékhoff and Mlle. Lévy were outstanding.

Tiffeneau was a man with wide interests, and t
scientific aspect of medicine made a special appeal
him. It is characteristic of his versatility that
worked in Richet's laboratory and also at the Paste
Institute, where it was at the suggestion of Ro
that he decided to qualify in medicine. In 1907
obtained his doctorate in science, and in 1910 h
doctorate in medicine. He was elected to a chair
chemistry at the Hôtel Dieu in 1924, and to a cha
of pharmacology and materia medica at the Sorbon
in 1926; for a man to have held at the same ti
those two important chairs, and to have achiev
distinction in each, is surely exceptional. In 19
he was Dean of the Faculty of Medicine of t
University of Paris. He was honoured by his electi
into the Académie de Médecine in 1927 and by h
selection as member of the Institut de France in 19
in succession to Urbain. He was also an Officier de
Légion d'honneur. At the time of his death on M
20, 1945, he was president of the French Chemic
Society. His wife, a sister of Prof. Fourneau, surviv
him with two sons.

After Fittig discovered the pinacol transformati
in 1859, the mechanism of this action as well as th
of the dehydration of glycols of various typ

racted the attention of many chemists the world r, and among those chemists Tiffeneau takes a ding place. Indeed, no one more than he had loited this important aspect of molecular re- angement so exhaustively and with greater experi- ntal skill and ingenuity. Some conception of his nprehensive outlook may be gathered from a rusal of the elaborate résumé on glycols which he ote for the "Traité de Chimie" edited by Grignard, pont and Locquin. By his studies on the semi- drobenzoin and semipinacolinic transpositions as ll as on the vinyl dehydration of glycols, he threw ich light on the question of distribution of affinity molecules. Further, the reaction of semipinacolinic amination furnished him with an excellent means contrasting the migrational aptitude of hydro- bon radicals. Among the numerous topics which investigated may be mentioned the isomerization epoxides, the elimination of halogen from iodo- drins, and the stereochemistry of compounds of e type of ethylhydrobenzoin. Dealing more par- ularly with hypnotics and anæsthetics, he advanced pharmacology by his work on the relationship between chemical constitution and physiological action, and he also experimented with the effects of adrenaline, ephedrine, hordenine, organic compounds of mercury, and many other substances.

Like Pasteur, Tiffeneau was a keen French patriot, and during the occupation of Paris by the Germans he did much to keep the spirit of research alive in the University. The news of his sudden death came as a blow to his many friends, who are not unmindful of what they owe to his inspiration.

ALEX. MCKENZIE.

WE regret to announce the following deaths:

Dr. F. W. Aston, F.R.S., fellow of Trinity College, Cambridge, on November 20, aged sixty-eight.

Dr. H. E. Durham, who took part in various expeditions to study tropical diseases, and in recent years was supervisor of the laboratories of H. P. Bulmer and Co., Ltd., on October 5, aged seventy-nine.

NEWS and VIEWS

obel Prize for Chemistry for 1944: Prof. Otto Hahn

PROF. OTTO HAHN, to whom the Nobel Prize for nemistry for 1944 has been awarded, in recognition his discovery (with F. Strassmann) of the neutron- duced fission of uranium and thorium (in its emical aspects), has for long been universally cognized as the outstanding 'radioactive' chemist his generation. Born sixty-six years ago, he began s studies in radioactivity in his early twenties under r William Ramsay at University College, London, oceeding from there, as Soddy had done previously, work for a time with Rutherford in Montreal. In ondon he discovered radiothorium, an intermediate oduct between thorium and thorium X, and in ontreal radioactinium—and also carried out purely ysical experiments on the magnetic and electric flexions, and on the ranges, of the α-particles from orium C. Having returned to Berlin (1906), he olated mesothorium 1 (1907) and mesothorium 2 908), and from that date he continued to contribute gularly to—and in general to lead—the great lvances in specialized chemical technique required r pioneering work with the heavy radioactive ements. His thirty years association with Lise eitner (1908–38) provides a classical example of the ppy collaboration of chemist and physicist to the utual advantage of both sciences. It was terminated ly by the rigour of the laws of racial discrimination hich were enforced in Hitler's Germany. No doubt is more than a slight consolation in the face of aposed separation that Meitner and Hahn should ich have been able to contribute, one on the physical, e other on the chemical side, to the original ucidation of the problem of uranium fission. uring the War, Hahn continued to work on the emical side of this problem and many of the sults which he and his colleagues obtained ere permitted full publication by the German nsor.

The award of the Nobel Prize is a fitting tribute to scientific achievement of immense range and singleness of purpose: Hahn may have missed the broader generalizations, the displacement law, the significance of nuclear isomerism—although he discovered the first recorded instance of this phenomenon (1921) and established its essential features as the result of masterly experimentation, he may, in later years, have been in possession of the clue to fission before he would admit it even to himself, but no single man has done more for his subject. In 1906, Rutherford wrote ("Radioactive Transformations", p. 69) "the results so far obtained by Hahn are of the greatest interest and importance"; his subsequent discoveries, over a period of forty years, have maintained that high standard throughout.

Nobel Prize for Physics for 1945: Prof. Wolfgang Pauli

THE Nobel Prize for Physics for 1945 has been awarded to Prof. Wolfgang Pauli, of the Federal Technical Highschool at Zurich, which before the War became through him a centre of theoretical physics. When the danger of a German invasion seemed imminent, he went to the Institute for Advanced Study, Princeton. Among the many brilliant disciples of Sommerfeld, Pauli and Heisenberg are the most outstanding. While he was a student, Pauli wrote the article on the "Theory of Relativity" for the "Mathematical Encyclopedia" which, to this day, is one of the best presentations of this subject. He took an active part in Bohr's interpretation of atomic spectra in terms of quantum theory, and he was the first to attribute to the electron, apart from its three ordinary quantum numbers, a fourth one, $s = \pm \frac{1}{2}$, which was, soon afterwards, recognized by Goudsmit and Uhlenbeck to be the angular momentum (spin). This led Pauli to his main discovery, the exclusion principle; originally derived from experimental facts about spectra (of helium and other atoms) it turned out to be one of the most general rules of quantum theory. It served Bohr as the main tool in his explanation of the periodic system of the elements. After Bohr's theory of electronic structures was superseded by quantum mechanics, Pauli's principle found its natural place in it as the postulate that the wave function of several electrons is skew in the co-ordinates of these. Later, Pauli has shown the close connexion between his principle and the statistics of ensembles, namely, that particles with integral spin (photons, mesons) satisfy Bose–Einstein statistics, while particles with half-integer spin (electrons, protons) satisfy Fermi–Dirac statistics.

Pauli also took part in the development of matrix mechanics. He was the first to treat the hydrogen atom by matrices, and he showed how in non-relativistic approximation the spin of the electron could be represented by a set of matrices, so paving the way for Dirac's relativistic theory of the electron. He has published papers on nuclear physics (hyperfine structure), equilibrium of radiation and molecules, paramagnetism of metals, quantization of field equations (with Heisenberg), wave equations of particles with higher spin, entropy in quantum statistics, and similar subjects.

Charles Chree Medal and Prize of the Physical Society: Dr. J. A. Fleming

THE Council of the Physical Society has awarded the third (1945) Charles Chree Medal and Prize to Dr. John A. Fleming; the presentation will be made on December 6. From about 1905 onwards, Dr. Fleming was the principal colleague of the late Dr. L. A. Bauer, the initiator and first director of the Department of Terrestrial Magnetism of the Carnegie Institution of Washington, whom he succeeded in 1932 as director and also as editor of the international journal *Terrestrial Magnetism and Atmospheric Electricity*. Dr. Fleming has been president of the International Association of Terrestrial Magnetism and Atmospheric Electricity of the Union of Geodesy and Geophysics since 1944 and general secretary of the American Geophysical Union from its inception.

Dr. Fleming's Department is the only institution in the world devoted to the study of terrestrial magnetism in all its aspects; and under him its work has been extended in new directions, including a wide programme of ionospheric study and both theoretical and experimental investigations in nuclear physics. The field-work undertaken by the Department has contributed greatly to the knowledge of the earth's magnetism where no magnetic surveys have been made and no permanent magnetic observatories exist. Much of this observational work was done under Dr. Fleming's direction; he controlled the organization and equipment of the teams of observers on land and shared in the design and the voyages of the non-magnetic ships *Galilee* and *Carnegie*, which made extensive magnetic surveys of the oceans for some twenty years, and in the planning and institution of the Department's magnetic observatories at Watheroo (Western Australia) and Huancayo (Peru). He has also helped and encouraged magnetic and atmospheric electric observation by official or private agencies in many lands. But for his work our knowledge of the state of the earth's magnetic and electric fields during the past forty years would be materially less than it is. He has also organized and stimulated the geomagnetic and electric researches undertaken by his Department, and notably in the elucidation of the short-lived magnetic effects associated with radio fade-outs and solar eruptions, and, in recent years, in radio scien Though it is not possible always to separate t work of Dr. Fleming from that of his staff, the uniq position which the Carnegie Institution maintai in the investigations of all the problems of terrestr magnetism is unquestionably due to his wise guidan and inspiring leadership.

Science Museum: Retirement of Col. E. E. B. Mackinto

THE many friends of Colonel E. E. B. Mackinto will learn with regret of his retirement from t position of director and secretary of the Scier Museum on November 30, on reaching the age lim He has held this position with distinction since 19 when he took over the directorship from Sir Hen Lyons, soon after the latter had successfully launch the Children's Gallery and introduced the idea special exhibitions. He extended and developed bo these features, and by 1939 had succeeded in evolvi an attractive and fascinating gallery, specially d signed and arranged for the younger visitors, a providing a most instructive elementary introducti to many branches of science. He has explored t possibilities of different types of special exhibitio and for a number of years has devoted one of t main galleries of the Museum entirely to this purpos During the period 1933–39, some thirty-five speci exhibitions were held in the Museum, not a few which met with outstanding success, and there no doubt that the policy of holding these speci exhibitions has been well justified. Under Colon Mackintosh's direction, the Science Museum co tinued to maintain and even to improve its positi in the forefront of the national museums and galleri of Britain, until the War necessitated its closure. Tl main task of the Museum at this time was to ensu the safety of its contents—objects, archives ar records alike—and Colonel Mackintosh succeeded dispersing approximately two thirds of the collectio together with more than 100,000 volumes from tl Science Library, to thirty isolated country house A selection of these possessions is now being broug back to London, in preparation for the partial r opening of the Museum. Colonel Mackintosh w have the good wishes of his many friends in h well-earned retirement.

Dr. H. Sha

THE Ministry of Education has announced t appointment of Dr. Herman Shaw as director ar secretary of the Science Museum as from December in succession to Colonel E. E. B. Mackintosh. T appointment of a professional man of science to th important office is a departure from past practic and will be generally welcomed. Dr. Shaw receiv his education at Bradford Grammar School and t Royal College of Science, where he studied physic During the First World War he served in the Roy Naval Air Service. He joined the staff of the Scien Museum in 1925, and later became 'keeper' of physic His special interest in physical research has been geophysics, and he was awarded the degree of D.S of the University of London for a geophysical resear using the Eötvös pendulum. He has long be associated with the Physical Society, of which present he is the acting treasurer; he also took active share in the organization of the Edinbur meeting of the International Union for Geodesy ar Geophysics in 1936.

Phillip Morris : Vice-Chancellor, University of Bristol

IT has recently been announced that the successor Dr. Thomas Loveday as vice-chancellor of the iversity of Bristol is to be Mr. Phillip Morris, the sent director-general of Army education. Mr. rris was appointed to the latter post in February 44 in order to co-ordinate the work of the Director-s of Army Education and the Bureau of Current fairs. He was educated at Tonbridge, St. Peter's, rk, and Trinity College, Oxford, and, after gradua-n, spent some time on the teaching staff of West-inster Training College. There he decided to take educational administration and joined the staff the Kent Education Committee as assistant educa-n officer. In due course he was promoted to istant director and in 1938 succeeded Mr. Salter vies as director of education. There, in the early ars of the War, he began those first contacts with my education which finally led to his accepting e position of director-general. While carrying out ese duties he won the admiration and respect of his colleagues. He combined a breadth of vision d acuteness of mind with an administrative ability ich is quite unusual. He went into the War Office a time when few regular soldiers would have dared say that they understood the organization and ministration of the modern army; he not only rprised everyone by the rapidity with which he asped the situation but also by the insight which brought to bear upon the problem of the Army's ucational needs. The comprehensive educational heme for the Army which is now in being is, to the derstanding person, a monument to Morris's keen-ss and ability. Mr. Morris hopes to take up his w appointment in January 1946. We wish him ery success in a post which, in the coming years, ll make great demands on his administrative ilities.

Chemical Research at Leeds

THE retirement of Prof. Whytlaw-Gray from the air of chemistry in the University of Leeds after tenure of twenty-two years (see *Nature*, Sept. 29, 386) will not mean his withdrawal either from the niversity or from active research; for the Lever-lme Trustees have awarded him a grant which will able him to devote himself wholely to research. n account of the accurate work on gases which s been carried out in the Chemistry Department Leeds over a number of years by Prof. Whytlaw-ay and his collaborators, Imperial Chemical Indus-es, Ltd., have recently made a generous offer to e University to finance and support a fundamental ece of research on the behaviour of gases and gas ixtures under high pressures and temperatures. is work will be undertaken by Dr. J. Colvin and r. J. Hume at the desire of Prof. Whytlaw-Gray. e firm will provide apparatus specially designed d made for this work at an estimated cost of £3,500, d will make an annual grant to cover the expenses the work. This invitation to Prof. Whytlaw-Gray's lleagues, following the establishment of the I.C.I. lowships, is additional evidence of the Company's nviction that industry should support the search ter knowledge for its own sake, which is so important part of the work of a university. Although the mpany is interested in this work in so far as it es gases at high temperature and pressure in me of their commercial processes, the research will not be directed with the view of producing commercially valuable information, since it is intended to provide fundamental knowledge; no restriction is imposed on the carrying out of the work or the publication of the results.

Chemical Engineering at the University of Leeds

A GIFT by Mr. Charles Brotherton of £55,000—£50,000 of which is under a seven-year covenant—to provide a new chemical engineering laboratory was announced at a recent meeting of the Council of the University of Leeds. The benefaction is in keeping with the recognition of the importance of the subject now general in Great Britain; the Universities of London and Cambridge have also benefited recently by endowments to provide for this field of study. The Department of Coal Gas and Fuel Industries with Metallurgy, which provides the course in chemical engineering, was established in 1906 to give training in fuel and metallurgy. In 1910 a degree in gas engineering was introduced, following the endowment of a chair by the British gas industry to perpetuate the memory of Sir George Livesey; this was followed later by contributions to a building fund. The degree course in gas engineering has been largely chemical engineering in character, and it was provided at a time when the latter subject met with little academic recognition. In 1942, the scope of the curriculum at Leeds was widened, and a four-year degree course in chemical engineering added to meet the needs of those passing either into the contracting side of the gas industry, or into the chemical industry generally. Among many other generous gifts to the University, Mr. Brotherton has already given liberal support to chemical and gas engineering. In 1942 he provided four undergraduate scholarships, and in 1943 a research assistantship; in 1944 he made a donation of £1,000 for equipment and £1,000 a year under a seven-year covenant for a Brotherton lectureship. Dr. J. S. Forsyth, at present Brotherton research assistant in chemical engineering, has now been appointed Brotherton lecturer in the University.

Research Fellowships in Engineering and Science

IN recognition of the increasing mutual dependence of universities and industry, Messrs. Turner and Newall, Ltd., of Rochdale, Lancs, manufacturers of asbestos, magnesia and allied products, have decided to give the necessary funds to provide a total of eight research fellowships in engineering, inorganic chemistry or physics or allied sciences. The fellowships will be financed by them for a period of seven years, and are to be established at specified universities in areas in which the company has certain of its larger factories; they will be known as 'Turner and Newall Research Fellowships'. The fellowships will be distributed among the following universities: Manchester (four), London (two), Leeds (one) and Durham (one). They will be of a normal value of £600 a year each, and the Universities will accordingly receive a total sum of £33,600 over the seven-year period for this purpose.

Science and War

PROF. J. D. BERNAL delivered a Friday evening discourse at the Royal Institution on November 23 on "Lessons of the War for Scientists". He said that the share that science had in the war effort can well be balanced by the contribution of the experience of war both to fundamental and applied science in times of peace. The War provided full-scale experience of organized science with the advantages of an over-all directing purpose and without the limitations of shortage of funds and apparatus. Not only was it found possible to apply existing discoveries to practical uses in a far shorter time, but also it was possible to carry out fundamental researches which revealed new factors underlying practical experience, such as, for example, the theory of shock waves and blast. A high degree of integration was reached between scientific men working in different fields, as also in different countries; and this was enormously facilitated by an improved organization of communication and by far greater facilities for travel and visits between men of science. Further, a directing organization of scientific committees grew up, which went far to combine principles of planning and freedom which had often been claimed to be incompatible.

This experience, Prof. Bernal said, extends and confirms what has already been claimed as to the advantages of improved organization and greater facilities for science; but in addition to this, the experiences of the War produced entirely new concepts of the relations between science and practical activities. These evolved, in the first place, out of the use in the field of complicated scientific apparatus, and became towards the end of the War the scientific examination of the objects and purpose of warfare and protection that we have come to know as 'operational research'. Operational research unites, on one hand, the physical, biological and social sciences in the most intimate way, and, on the other, integrates the scientific with the economic and technical fields. The problem that we have now to solve is how to conserve all the advantages and the lessons we have had from war science to deal with the problems of peace, where, though the urgency is not so violent, there is a far greater diversity of problems and a far greater need to take the various and often conflicting desires of people into account.

World Power Conference

A MEETING of the International Executive Council of the World Power Conference was held during November 20–21, to discuss the post-war revival of the activities of the Conference. Sir Harold Hartley, the chairman of the Executive Council, presided; some twenty countries were represented, including Australia, Belgium, Canada, Czechoslovakia, Denmark, France, Great Britain, India, Ireland, Luxemburg, Mexico, the Netherlands, New Zealand, Poland, South Africa, Sweden, Switzerland and the United States. Mr. Harold Hobson, chairman of the Central Electricity Board, led the British delegation. It was decided to hold, if possible, a sectional meeting in 1947 to discuss the general question of fuel economy; the place of this meeting will be decided at a meeting of the Council to be held in Paris next spring. Before the War the Conference published a statistical yearbook containing data on all sources of energy, giving both natural resources and annual production; publication will be resumed as soon as possible. The following resolution was passed unanimously: "In view of the future significance of atomic energy over the whole range of power problems this Council resolves to appoint a small committee to watch developments and to make recommendations to the International Executive Council of the World Power Conference as soon as it is practicable to have an effective discussion of the utilisation of atomic energy for industrial and domestic purposes".

The Night Sky in December

NEW moon occurs on December 4d. 18h. 06m. U and full moon on Dec. 19d. 02h. 17m. The followi conjunctions with the moon take place: Dec. 3d. 09 Venus 2° S.; Dec. 20d. 21h., Saturn 2° S.; De 21d. 12h., Mars 0·7° N.; Dec. 27d. 21h., Jupit 4° S. In addition to these conjunctions with t moon, Mercury is in conjunction with Venus Dec. 13d. 04h., Mercury being 2·1° N. Occultatio of stars brighter than magnitude 6 are as follow Dec. 17d. 18h. 26·0m., ε Taur. (*D*); Dec. 31d. 6 50·1m., ν Scor. *m* (*D*). *D* refers to disappearance, a the times are for Greenwich. Mercury is in inferi conjunction with the sun on Dec. 7 and is stationa on Dec. 17. The planet sets about 35 minutes after t sun at the beginning of December and rises abo one and a half hours before the sun at the middle a end of the month. Venus rises at 6h. 22m., 7h. 04 and 7h. 42m. at the beginning, middle and end of t month respectively. Mars, in the constellation Cancer, can be seen throughout the night, rising 19h. 45m. on Dec. 1 and at 17h. 13m. on Dec. 3 The planet is stationary on Dec. 5. Jupiter, in t constellation of Virgo, can be seen in the early mor ing hours, rising at 3h. 11m. on Dec. 1 and 1h. 38 on Dec. 31. Saturn, in the constellation of Gemi can be seen in the evening hours, rising at 19h. 11 on Dec. 1 and at 17h. 02m. on Dec. 31. There w be a total eclipse of the moon on Dec. 18–19, visib at Greenwich. The circumstances of the eclipse a as follows:

Moon enters penumbra ..	Dec. 18d.	23h.	38.4m.
Moon enters umbra ..	19	00	37.5
Total eclipse begins ..	19	01	40.5
Middle of eclipse	19	02	20.3
Total eclipse ends	19	03	00.2
Moon leaves umbra ..	19	04	03.1
Moon leaves penumbra ..	19	05	02.3

The winter solstice occurs on Dec. 22d. 05h. Th Geminid meteor shower reaches a maximum abo Dec. 12–13.

Announcements

SIR JOHN ANDERSON will deliver his postpone address on "Research in Relation to Reconstruction in the Whitworth Hall of the University of Ma chester on December 6. The meeting has bee arranged by the Manchester Joint Research Council cards of admission are obtainable from the Secretar of the Council, c/o Manchester Chamber of Commerc Ship Canal House, King Street, Manchester 2.

THE Lords Commissioners of the Treasury hav approved the appointment of Mr. W. F. Grime formerly of the National Museum of Wales, Cardi to be keeper and secretary to the London Museu from December 1.

DR. JAMES GREIG has been appointed to th University chair of electrical engineering tenable a King's College, London, as from October 1. Durin 1926–39 Dr. Greig was lecturer in electrical enginee ing at the University of Birmingham, and since 193 he has been head of the Engineering Department a Northampton Polytechnic.

THE Society for Visiting Scientists, 5 Old Burlingto Street, London, W.1, has arranged a series of meeting to discuss the organization of research within th British Commonwealth. Each area will be dealt wit by speakers having special knowledge of it. Th meetings will be held at 7.30 p.m. on December (India and the Colonies), December 19 (Australia an New Zealand), January 9 (Canada and South Afric and January 23 (Great Britain).

LETTERS TO THE EDITORS

opagation and Termination Coefficients for Vinyl Acetate Photopolymerization

MOST vinyl derivatives polymerize to macro- ecules by means of the well-recognized chain chanism in which the monomeric molecules are ivated thermally, by catalysts or by radiation. is step is followed by the addition of molecules monomer, the so-called propagation step, and ally the activity may be removed by a variety of ys leading to the termination of growth of the ymer. In many such reactions termination of wth occurs by mutual reaction between the two ive polymers. In this case it is easy to show that

$$- d(M)/dt = k_p(M)(I/k_t)^{1/2},$$

ere $- d(M)/dt$ is the rate of disappearance of nomer, I is the rate of activation of monomer k_p is the average value of the bimolecular velocity fficient for the interaction of active polymer and nomer and k_t is the termination velocity coefficient. transfer is excluded, the chain-length ν is $M)/(Ik_t)^{1/2}$. Thus measurements of the rate and the chain-length will enable $k_p/k_t^{1/2}$ to be determ- d. No matter how the experiments are conducted, y *two* quantities can be measured, whereas there *three* variables concerned in these complex re- ions. Complete analysis of the kinetics of the ction is therefore impossible. The following tech- que has made it practicable to overcome this funda- ntal difficulty and to learn a good deal more about mechanism of polymerization.

According to the above general theory, we have relationship that

$$- d(M)/dt = k_p(P)(M),$$

ere (P) is the total active polymer concentration. rther, we have that $I = (P)/\tau$, where τ is the mean of the active polymer. Thus if I and τ can be ermined, k_p and k_t can be computed by substitu- n in the above equations. The photochemical uid phase polymerization of vinyl acetate proved be a suitable reaction for this purpose. In this e, $- d(M)/dt$ is proportional to the square root the intensity of the absorbed radiation. τ can, this circumstance, be measured by the rotating tor method, and, in a typical experiment, had a ue of $2{\cdot}25 \times 10^{-2}$ sec. I was determined by the ndard inhibition technique. *p*-Benzoquinone is ecially useful for this purpose since it gives rise a well-marked induction period followed by a rate olymerization precisely equal to that of the un- ibited reaction.

t turns out that each quantum of absorbed radiation rts off a polymer chain. In the experiment above, $= 6{\cdot}3 \times 10^{-7}$ einstein sec.$^{-1}$ litre^{-1}. At 15·90° C., $l(M)/dt$ was $8{\cdot}3 \times 10^{-6}$ moles sec.$^{-1}$ litre^{-1}. Thus, $= 5{\cdot}86 \times 10^2$ litre moles^{-1} sec.$^{-1}$. These experi- nts were repeated at different temperatures in er to obtain the energy of activation for propaga- , which amounts to 4,400 cal. Hence the tempera- e-independent factor for k_p has a value of 5 × 10^6 litre moles^{-1} sec.$^{-1}$. If we assume the mal value of this factor to be 10^{11}, then this ld imply a steric factor of about 10^{-5}, which is reasonable having regard to the nature of this type of reaction.

From the theory, $k_t = (k_p^2(M)^2I)/(- d(M)/dt)^2$. The value of k_p is then inserted in this equation and k_t is $3{\cdot}04 \times 10^9$ litre moles^{-1} sec.$^{-1}$.

Experiment shows that *no* energy of activation is required for the termination reaction, and hence the steric factor will have a value of about 10^{-2}. These measurements refer to a chain-length of 1,250. All these experiments were repeated at a chain-length of 2,500 by reducing the intensity of the light to a quarter of its original value, τ increasing to $5{\cdot}51 \times 10^{-2}$ sec. Under these conditions, $k_p = 5{\cdot}56 \times 10^2$ and $k_t = 2{\cdot}86 \times 10^9$. In spite of the large increase in chain-length, it will be seen that the values of k_p and k_t are not much affected. Further, the ratio of these constants remains unaltered, which is very convenient when dealing with the detailed theory of the reaction.

The number average molecular weight of these photopolymers was determined by Mr. C. R. Masson (details will be published in a separate communication) in this laboratory, and it is interesting to note that they agree to within 5 per cent of the kinetic chain-length. This shows quite conclusively that no transfer reaction takes place under these conditions. In addition, these figures prove that when the active polymers mutually destroy each other's activity, they do not link up but remain separate particles.

These facts could be readily explained by assuming that the active polymers are free radicals, but such experiments do not necessarily indicate conclusively the nature of the active particle.

Full details of these experiments will be published elsewhere.

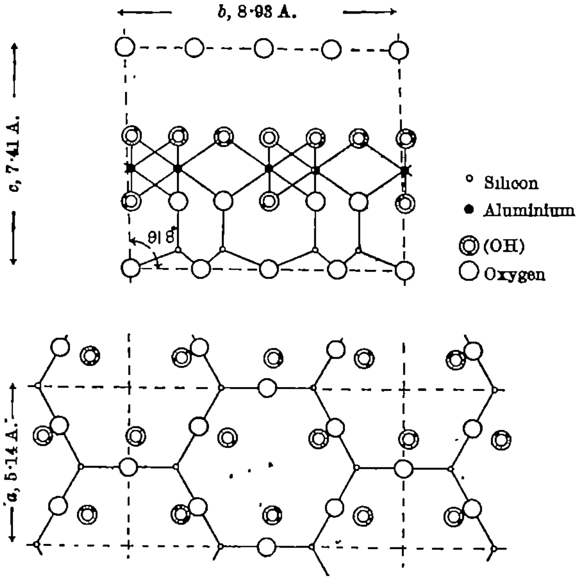
Structure of Kaolinite

THE generally accepted structure of kaolinite was elucidated by Gruner[1] from X-ray powder photographs, and Hendricks[2] afterwards gave confirmatory data obtained by electron diffraction. They find a monoclinic structure with cell dimensions $a = 5{\cdot}14$ A., $b = 8{\cdot}90$ A., $c = 14{\cdot}51$ A., $\beta = 101°\ 30'$, consisting of sheets of Si-O tetrahedra and Al-OH octahedra arranged parallel to the basal plane (001), there being two sheets in each unit cell. Gruner based his structure on measurements of some forty reflexions. Other workers[3] have since published lists of kaolinite reflexions aiming at higher accuracy in the spacing measurements rather than increasing the number of recorded reflexions. Apart from the work of Hendricks, we know of no further attempt to study the structure of the mineral since the publication of Gruner's analysis.

We have recently had occasion to examine in detail the X-ray powder diagram of kaolinite under conditions of higher resolution than Gruner employed; using a 20-cm. diameter focusing camera and a 12-cm. diameter cylindrical camera, we have recorded some seventy reflexions. Among the lower-order reflexions in particular we find additional lines to those recorded by Gruner, and attempts to reconcile them with a monoclinic cell failed completely. We were finally led to examine the possibility of a triclinic



cell. The observed reflexions can be accounted for satisfactorily by the following triclinic cell:

$a = 5·14$ A. $\alpha = 91·8°$
$b = 8·93$ A. $\beta = 104·5°$
$c = 7·41$ A. $\gamma = 90°$

This differs from Gruner's cell in that it is only pseudo-monoclinic and, having half the height, contains only one Si-O, Al-OH sheet. The structure of the sheet, shown in the upper part of the accompanying diagram, is that given by Gruner; the lower part of the drawing shows the relation between the basal oxygen atoms of the cell and the OH layer of the cell immediately *below* and may be compared with similar diagrams given by Hendricks[4] for the other kaolin minerals, dickite and nacrite, which show a closely similar relation between the two adjacent layers. Calculation of the reflected intensities for the ideal structure (that is, assuming regular tetrahedra and octahedra) shows general agreement between the observed and calculated intensities. A more detailed study of the actual deviations from the ideal structure is in progress.

The triclinic character of the lattice results in many more reflexions than would occur if the structure were strictly monoclinic, and provides a general explanation for the broadness of many of the observed lines, which are composite, and also (at least, in part) for the weakness of many of the lines as compar for example, with those from dickite, a strictly mo clinic kaolin mineral.

LATTICE SPACINGS, *d*, AND OBSERVED INTENSITIES, *I*, OF X-RAY REFLEXIONS FROM KAOLINITE.

A comparison of our results with those of Gru for the lower order reflexions is given in the acco panying table.

Whether the kaolinite examined by Gruner ha different structure from the specimens we h examined is for the moment left an open questi We are examining a large number of kaoli specimens from widely different localities, and so they have confirmed our results given above, wh were obtained from a sample of specially puri Cornish china clay; none has so far confir Gruner's data.

Note added in proof. We have now exami fifteen kaolinites from different localities, and results confirm those given above.

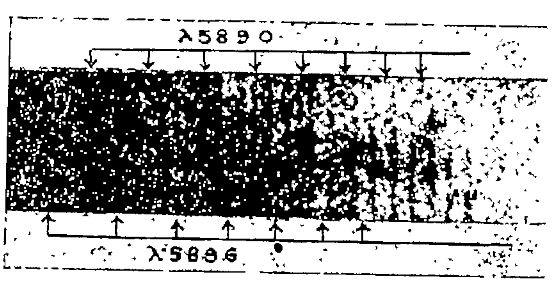
Splitting of the Sodium Doublet Lines

WHILE demonstrating the interference patter of various lines by means of a Hilger C. instrument in conjunction with a Lummer-Gehrc plate, a Philips 'Philora' sodium vapour la was used to produce the patterns of the sodiu doublet λ 5890/96. This lamp is in the form of U-tube enclosed in an outer vacuum jacket and excited by 230 V. A.C. mains through the usu electric control gear. The lamp usually takes abo 10–12 minutes to reach its maximum intensity. the first few minutes, each of the two lines show its normal monochromatic interference pattern sharp fringes; but as the lamp got heated and acquir its steady state of illumination, the fringe system both the lines presented a complex appearance. follow this development of complexity, the lamp w switched off for some time to cool down and th restarted. The fringe pattern was viewed throu the telescope from the time it was switched on. the lamp gained its full wattage (65 W.), each of t fringes in the two wave-lengths began to broad out and ultimately developed almost symmetric splitting into two defined components. The magnitu of the actual splitting computed from measureme is, within the limits of experimental errors, 0·064 for λ 5890 and 0·053 A. for λ 5896.



At first sight, this effect suggests self-reversal com-aed with pressure broadening; but the discharge nditions were not quite favourable for partial self-sorption. As Finkelnburg[1] points out, self-reversal y also be a consequence of partial pressure of tallic vapour in the path of discharge; absence self-reversal may leave the lines merely broadened, ring a diffuse appearance of continuous spectrum to e fringes, which is not the case found here. If, how-er, a genuine self-reversal is assumed, it would be ite interesting to investigate the broadening in this rticular case owing to the nature of the radiation urce. As shown by Watson[2], broadening may be aced to a number of factors: (*a*) radiation damp-g, (*b*) Doppler effect, (*c*) resonance between similar oms, (*d*) effect of foreign perturbers of van der aals type, any one or several together contributing the effect.

On the other hand, if self-reversal is ruled out, we ght interpret the observed phenomenon as a litting of the Stark effect type by foreign perturbers ere neon) carrying permanent fields. There is idence in favour of this type of broadening by ter-atomic or inter-molecular fields resulting from en mild electrical excitation. Merton[3], Hulbert[4] and nkelnburg[1] have recorded inter-atomic Stark fects of the Balmer lines of hydrogen, and Finkeln-urg[1] has deduced from the observed broadening the ectric fields at various pressures. The great line-eadths of Hg in high-current discharge by strong ter-atomic or ionic fields have been observed by nauss and Bryan[5]. Even splitting of the λ 2537 Hg sorption line into two broad components in solu-ons has been shown by Reichardt and Bonhoeffer[6]. Other similar lamp sources such as mercury and dium (another pattern) examined in this way show mparable splitting or broadening effects of smaller or rger magnitude. It is not possible at this stage to y what the predisposing causes of the phenomenon e, until complete experimental analysis under de-ied conditions is available. This is being undertaken.

nhancement of the Action of Immune Hæm-Agglutinins by Human Serum

EXPERIMENTS to determine whether human mplement plays a part in the specific agglutination human erythrocytes by immune serum revealed an teresting phenomenon. The titration end-point of e immune iso-agglutinin chosen for the experiment s found to be considerably increased when certain mpatible human sera, diluted 1 : 3, were used in ace of saline as a diluent for the iso-agglutinin. When turally occurring iso-agglutinin was titrated in rum, however, the titre was found to be the same that observed using saline as diluent (see Table 1). Seventy-seven immune sera, comprising 49 anti-*Rh*, anti-*Rh* sub-group, 14 anti-*A*, 1 anti-*B*, 3 anti-A_1 (*alpha*$_1$), 2 anti-*M* and 1 anti-*N*, were titrated in serum and in saline. The degree of agglutination as measured by the size and firmness of the masses of agglutinated cells was in each instance much more pronounced when serum was employed for dilution than when saline was used, and in 73 of the 77 specimens there was also a definite increase in titre. Frequently, however, the limit of agglutination in serum was observed to extend to not more than one or two tubes beyond the limit of agglutination of the saline control series.

TABLE 1.

Titre	Immune iso-agglutinin		Naturally occurring iso-agglutinin	
	Saline	Serum	Saline	Serum
1	*c*	*c*	*c*	*c*
2	*v*	*c*	*c*	*c*
4	+	*v*	*v*	*v*
8	(+)	*v*	+	(+)
16	*w*	*v*	*w*	*w*
32	—	++	—	—
64		(+)		
128		(+)		
256		*w*		
512		—		

Read macroscopically: *c* = complete agglutination; surrounding fluid clear. *v* = visual agglutination; surrounding fluid pink.
Read microscopically: ++ = very large clumps; + = large clumps; (+) = smaller clumps with many free cells; *w* = clumps of 4–5 cells; — = no agglutination.

Fourteen naturally occurring agglutinins, which included 5 anti-*A*, 4 anti-*B*, 4 anti-A_1 (*alpha*$_1$), and 1 anti-0, were also examined. Two of the anti-A_1 (*alpha*$_1$) sera were prepared by absorption of group *B* sera with A_2 cells and two were from group A_2B persons. The anti-0 serum was an absorbed cattle serum. In no instance was there any increase in either the degree of agglutination or in the titre when serum was used as diluent in place of saline. The results are summarized in Table 2.

TABLE 2.

Iso-agglutinin	Total no. tested	No. showing increase in titre	No. showing *no* increase in titre
Immune anti-*Rh*	49	46	3*
Anti-*A*	14	13	1*
Anti-*B*	1	1	0
Anti-A_1	3	3	0
Anti-*M*	2	2	0
Anti-*N*	1	1	0
Naturally occurring anti-*A*	5	0	5
Anti-*B*	4	0	4
Anti-A_1 (α_1)	4	0	4
Anti-0	1	0	1

* These sera showed an increase in degree of agglutination, without an increase in titre being observed.

An immune *Rh* serum was titrated in 67 sera to determine whether the capacity to increase the agglutination titre of the immune iso-agglutinin was shared equally by all human sera. It was found that the sera varied markedly in their power to amplify the immune agglutinin, and indeed two very active sera were found to increase the titre of the test *Rh* serum from 4 to 256.

The factor present in the serum which causes the increase in titre is not complement as it is not destroyed by heating at 56° C. for half an hour, or by storing the serum frozen solid (— 10° C.) for many months.

The fact that no difference was observed in the titre of naturally occurring antibodies whether titrated in saline or serum indicates that the increase in titre shown by immune agglutinins cannot be ascribed simply to the effect of the viscosity of the serum.

The differentiation of natural and immune agglutinins by their behaviour in agglutination tests suggests that there is a qualitative difference between naturally occurring and immune agglutinins.

In suspected cases of hæmolytic disease of the newborn, the finding of *Rh* agglutinins in the maternal serum strongly supports the clinical diagnosis, but their presence in a serum is often doubtful when the degree of agglutination is very weak. In several instances during the last two years, we have used the agglutination enhancement test and have established beyond doubt the presence of *Rh* agglutinins in such weakly reacting sera. Also, in cases suspected of having received an incompatible blood transfusion, an anti-*A* or anti-*B* titre in the recipient's serum which is increased by the use of this technique is a strong indication that the antibody has been stimulated by immunization and that blood of an incompatible *A*,*B*,0 group has in fact been given.

A detailed account of the work described in this communication will appear elsewhere.

Transition of Fibrinogen to Fibrin as a Two-Step Reaction

It has been assumed by Apitz[1] that the transition of fibrinogen to fibrin is not a simple reaction, but takes place in two stages. The primary product should be a soluble substance, less stable than fibrinogen, which he called profibrin. By suitable choice of the composition of the electrolytes of the medium, we succeeded in studying the two phases of the reaction separately; thus we obtained a substance which has a better-founded claim to the name profibrin.

At a *p*H on the acid side of the iso-electric point of fibrinogen, for example, at *p*H 5·1, the addition of thrombin to a solution of fibrinogen does not cause clotting. If now the system is neutralized, say *p*H 6·8, the fibrinogen coagulates, which shows that at the acid reaction it has not been irreversibly damaged.

If the neutralization is not carried out immediately, but after a longer reaction at *p*H 5·1, then the clotting-time after neutralization is the shorter the longer fibrinogen and thrombin have been kept together at the acid *p*H (see table):

Composition of the system: 0·5 cm.^{3} fibrinogen according to Laki*, 20 mgm. per cm.^{3} in 0 9 per cent sodium chloride; 0 5 cm.^{3} *M*/5 potassium dihydrogen phosphate; 0·1 cm.^{3} thrombin. After different times of reaction, neutralization of 0·1 cm.^{3} of the reaction mixture with 0·05 cm.^{3} *M*/5 disodium hydrogen phosphate.

Reaction time:	Clotting time:
10 sec.	6 min.
1 min.	5 ,,
10 ,,	4 min. 30 sec.
30 ,,	3 ,, 30 ,,
60 ,,	2 ,,
90 ,,	40 ,,
120 ,,	15 ,,
300 ,,	10 ,,

* Laki, *Z. physiol. Chem.*, 273, 95 (1942). *Stud. Inst. Med. Chem. Szeged*, 2, 27 (1943).

This shows that the formation of fibrin takes place in two steps; the first step, the primary reaction between fibrinogen and thrombin, also takes pl at *p*H-values on the acid side of the iso-electric po of the former; the polymerization of the prim product to fibrin, however, is possible only th when the fibrinogen is negatively charged.

At *p*H 5·1 the presence of thrombin does cause any physical change of the fibrinogen wh could be considered as an indication that polymer tion was beginning. The viscosity at a very velocity-gradient shows only a slight increase[2].

The second phase of the transition is inhibited neutral salts in such a way that we conclude that polymerization of the primary product to fibrin caused by electrostatic attraction. The first react is not inhibited by electrolytes; its nature is obscure.

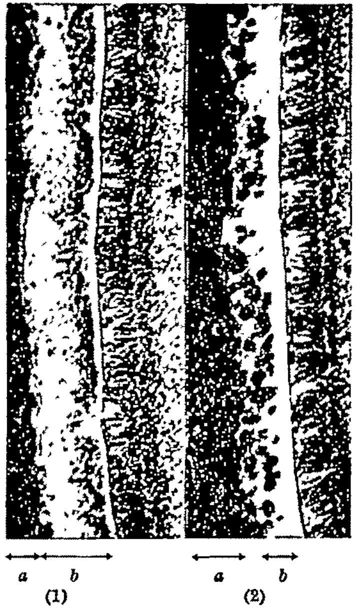
Effect of Restriction of Food Intake up the Incisor Teeth of Rachitic Rats

In previous publications[1], it has been shown th the upper incisor teeth of rats are very sensiti indexes of calcium and phosphorus metabolism. Th in rats on the Steenbock and Black rachitogenic d No. 2965[2], doses of vitamin D cause a response whi so far as present work goes, seems to be specific this substance. A line of newly calcified dentin occu in the proximal labial predentin formed after dosag but little change takes place in that already form (Fig. 1). This reaction is accompanied by the usu epiphyseal healing made use of in the line te Changing the Ca : P ratio of the diet given to rachi rats from 5·6 to 1·9 also causes healing in the tee and bones, but quite unlike that after vitamin medication. In the teeth, irregular clumps of cal spherites are laid down promiscuously in the proxim labial predentin. In the bones, an irregular heali occurs in the epiphysis, usually consisting of u growths of calcified material in the metaphysis, jo ing with that in the diaphysis, and often no cl 'line' occurs at all[3].

It appeared to be of interest to compare th changes with those occurring during restriction food intake,, which is well known to cause heali of rickets in rachitic animals. Three litters of r were kept on the Steenbock and Black diet un they had well-marked rickets. Some were then dos with 27 I.U. of vitamin D in oil by mouth and ma tained on the same diet. The rest were also kept the rachitogenic diet, but their food intake was restricted that they lost on an average 3·6 gm. weight per day. Animals treated in either way we killed and examined on the first, second, fourth, six or eighth days after dosage or food restriction. two of the litters the epiphyses of the restricted r showed new calcification on the second day, and the fourth day in the third litter. The changes we quite typical of those seen after vitamin dosage, with lines forming on the metaphyseal s



LONGITUDINAL SECTIONS OF THE PROXIMAL PART OF THE LABIAL SIDE OF THE UPPER INCISOR TEETH. *a* = DENTIN, *b* = PREDENTIN. × 90.

1) Section from a rachitic rat given 27 I.U. of vitamin D four lays previously. The line of new calcification can be seen in the predentin. (2) Section from a rachitic rat the food intake of which was restricted for two days. The irregular masses of calcospherites in the predentin can be seen.

the epiphyseal cartilage, and the two reactions re in fact indistinguishable. The line test became sitive on the fourth day in all animals dosed with tamin D.

The upper incisor teeth of the restricted rats acted within a few hours of dietary restriction. The eth of the animals dosed with vitamin D also acted within a few hours. The changes in the teeth the restricted rats were quite unlike those following vitamin D dosage, but were the same as the anges already described when the Ca : P ratio of e diet was adjusted[3]. In the proximal and intermediate part on the labial side, masses of interobular dentin gradually filled the whole of the prentin, starting from the already calcified dentin and orking, with time, across towards the odontoblasts ig. 2).

The changes in the blood calcium and phosphorus rachitic rats when the Ca : P ratio of the diet is justed are the same as those which occur when ch animals are starved. Kramer, Shear and Siegel[4] ve shown that the blood calcium falls and the osphorus rises in both cases. The animals may have tany, and in the present experiments several of e restricted animals appeared to be on the verge of tany. Thus on chemical grounds, it is easy to plain the resemblance of the reactions in the teeth th both treatments. It is, however, difficult to derstand the differences in the responses in the iphyses, and why the epiphyses of the restricted ts should react in a way identical with that after tamin D dosage when the chemical changes in the ood are so different. One would have expected change similar to that after adjusting the Ca : P tio of the diet.

So far as the teeth are concerned, however, the parative histological changes seen after vitamin D sage or dietary restriction in rachitic rats seem to have quite different mechanisms. Dietary restriction and adjustment of the Ca : P ratio of the diet, on the other hand, produce the same changes.

Utilization of the Slipper-Limpet (*Crepidula fornicata*) as Food as an Aid to the Recovery of Oyster-Culture in the Thames Estuary

AN account was given in *Nature*[1] of the very heavy mortality of oysters on certain Thames Estuary oyster beds following and directly attributable to the very severe winter of 1939–40. The financial loss was of a crippling nature, and attention was directed at the time to the need of oyster farmers for financial assistance from the Government for the recovery and restocking of the beds.

During the War, oyster cultivators have had to surrender most of their man-power, with the result that culture has been limited to certain parts of the oyster beds. In these circumstances, as I have found in a recent survey, the American slipper-limpet (*Crepidula fornicata*) has increased on the unworked beds in such numbers as to make dredging for oysters uneconomical while at the same time the total stocks of oysters have remained low. Thus there is greater need for assistance now than in the early years of the War, and in the first place for the cleaning-up of the grounds.

It is now suggested that a practical scheme to help towards the recovery of the oyster-beds is to utilize the slipper-limpet as food and thereby at least partially defray the costs of clearing the grounds. During the War, Korringa[2] has described how the slipper-limpet—which had invaded and spread rapidly on the Dutch oyster-beds since 1929 [3] as foreshadowed by me—became economically valuable as food, being either eaten raw or used in the manufacture of food products. The scale of the slipper-limpet utilization has increased enormously (4,500,000 kilograms were used in 1941 and 14½ million kilograms in 1942). In the early period slipper-limpet meats were separated manually; but later, mechanical devices were used with a great saving in man-power costs (letter from P. Korringa).

While the slipper-limpet, either cooked or raw, makes little appeal to the English palate, it seems possible that during the existing shortage of food-materials in Europe the flesh should have a reasonably high value at the present time when suitably worked up as meat product. Such a product was actually produced by a German firm which, however, kept the process secret; but this is not a serious hurdle.

The practical aspect of the problem is that it will exist only for a relatively short period. Although many hundreds of tons of slipper-limpets could be dredged, the supply would sooner or later fall below an economic minimum, though in this period the beds would be cleared. Hence the problem is essentially one for assistance as a post-war measure.

It is estimated from Korringa's data that dried protein constitutes about 1 per cent of the net weight of slipper-limpets, and as thirty tons of limpets could easily be dredged in a day with appropriate gear, a considerable daily quantity of food-material could be produced; the rate of supply could be adjusted within wide limits to meet the requirements of the manufacturing process.

The object of this communication is to direct the attention of the various bodies likely to be interested to the problem with the view of facilitating early action. These bodies are: Ministry of Agriculture and Fisheries as representatives of public oyster beds, and oyster cultivators; Ministry of Food, representing untapped sources of food supply; Department of Scientific and Industrial Research, as concerned in processes of food manufacture; Development Commission, as the body interested in researches dealing with improvements in fisheries; as well as private manufacturers of food products, and representatives of the oyster cultivators whose beds require clearing.

It is obvious that if these limpets could be used as food there would result the double advantage of contributing to the food stocks of Europe and helping the oyster farmers to clear their beds of this pestilent but extremely interesting immigrant from America.

I am indebted to Dr. P. Korringa for recent information relating to the Dutch oyster beds.

The Anti-Chromatic Reflex

IT has long been a matter for surprise that the eye appears to be so perfectly achromatized. It was this which led Euler to conclude that the construction of achromatic lenses must be possible, and in consequence the optician Dollond sought for a method, and thus invented the use of negative flint lenses in association with positive crown glass ones. The celebrated cobalt-blue glass experiment and many others amply demonstrate the fact that the lens system of the eye is uncorrected for colour. It was this fact that presumably led to the remark, which is often ascribed to Helmholtz, that if a lens maker turned out so inferior a lens as that of the eye he would soon be out of business.

Actually the performance of the eye as used in normal vision is of a very high order. Achromatizing the eye by means of a suitable combination of crown and flint glasses improves visual acuity to a very slight extent only. The same is true when monochromatic light, for example sodium light, is used for visual purposes. Further, the resolving power of the eye is only slightly inferior to that of an apochromatic microscopic objective of the same focal length and aperture. But in one important respect the lens system of the eye is greatly superior to such a microscopic objective, namely, in its angle of view, for this in the case of the eye exceeds 100° from the optic axis.

Many explanations have been offered in the p
for the absence of coloured fringes from the reti
image. But none of these has proved to be sa
factory. The experiments which I have repor
previously, in which micro-stimuli have been
ployed[1,2], have now led to the discovery of a nerv
reflex which has the effect of eliminating the colou
fringes produced by the chromatic aberration of
eye. Because of this effect, it has been called '
anti-chromatic reflex'. This reflex consists of
apparently separate mechanisms, one for dealing w
the yellow fringe, and the other for dealing with
blue one; these are the colours of the fringes no
ally present in the emmetropic eye. In the un
rected myope the fringes may be red and blue-gre
and in the uncorrected hypermetrope they may
green and purple, or even blue-green and red.
these conditions the anti-chromatic reflex will pr
ably fail to eliminate the fringes, so that they
be visible to the observer.

The mode of operation of the reflex may be
plained by taking an example. Suppose the obj
looked at to be a white dot on a black backgrou
then the image formed on the retina, owing to
chromatic aberration of the lens system of the e
will consist of a bright yellow dot surrounded by
blue halo of low intensity. The anti-chroma
reflex will now convert the yellow dot into a wh
one, and at the same time the blue halo will
replaced by black; thus the original appearance
the object will be restored.

It is hoped to publish further details of this ref
shortly.

Early Observation of Antibiotic Actio

IN his book "Essays on the Floating-Matter of t
Air" (1881), the physicist John Tyndall descri
experiments which he carried out in 1875 refuting t
doctrine of spontaneous generation of life. In t
course of these experiments tubes of organic infusi
were infected with organisms after exposure to t
atmosphere. A number of cases occurred when su
tubes, which were turbid and swarming with bacter
became covered with *Penicillium glaucum*, three
specified kinds being noticed. The bacteria in the
tubes lost their translatory power and fell to t
bottom, leaving the liquid between them and t
superficial layer clear. Tyndall ascribes this to t
success of the moulds in the struggle for existence a
notes that access of oxygen to the body of fluid m
have been hindered. He did not, however, test t
clear liquid for its capacity to support newly implant
bacterial life. It is interesting to speculate up
what the consequences might have been had Tynd
allowed himself to be drawn from his main investi
tion.

ATIONALIZATION OF MINERAL RIGHTS

July 1944 the Institution of Mining and Metal-urgy discussed a paper by Prof. W. R. Jones in ch he advocated the acquisition by the State of eral rights. On that occasion he restricted his posals to minerals as contrasted with *rocks* and so not include roadstones, building stones, limestone, k clays, sands and gravels. In a later paper mitted for discussion in September of this year, has extended his advocacy of nationalization to larger group.

t is noted that Great Britain is almost unique in British Empire in that the mineral rights are not ted in the Crown or in the Government. Two ortant steps have already been taken towards ionalization. Under the Petroleum Production of 1934 the ownership of petroleum occurring in tain is vested in the Crown ; under the Coal Act 1938 the State purchased the mineral rights in l by compensating the royalty owners on a basis a fifteen-year purchase of royalties. In addition, as long been accepted that the royal metals, gold l silver, and also any minerals lying under tidal erritorial waters, belong to the Crown. Prof. Jones v advocates the acquisition of all mineral rights the same basis as that used in the case of coal. is careful to point out that State acquisition of eral rights has nothing to do with nationalization mines.

n the earlier paper Prof. Jones deals mainly with d-zinc, tin and china clay. In the case of lead-zinc, s urged that low-grade ores remain to be worked, ich it is in the national interest to use but which mot be done except under a large co-ordinated eme involving drainage and centralized smelting. the case of tin he deduces from the now well-known enomena that copper lodes give place in depth to lodes with a relatively barren zone separating two, that rich tin deposits may underly many abandoned copper mines in the south-west of gland ; but that the problem is a national one ich could be tackled only after the acquisition of mineral rights.

n the second paper Prof. Jones mentions, though does not perhaps stress sufficiently, the profligate ste of land now resulting annually from the working gravel, sand, iron ore and other surface minerals. The most startling feature of the papers is the atively small cost involved. The figure for all se-metal minerals is only £421,000 ; for iron ore than £4,000,000, and for all the minerals of itain less than £22,000,000.

f the policy is regarded as right for coal and oil, seems difficult to resist the conclusion that it is ht for other minerals, but it would seem that of. Jones has only considered part of the problem. e State acquisition of petroleum rights was made *ore*, and in intelligent anticipation of, the discovery petroleum in quantity ; and no land owner could thfully feel himself unjustly deprived of his htful possessions since he did not know such sted. Prof. Jones's proposals deal with acquisition the State of other mineral rights by payment to ners in known mineral-bearing areas. It is here t a link with the general trend of policy regarding d planning suggests itself. If the State were to quire all development rights in undeveloped land at is, on land which is at present agricultural or afforested or open) and thus effectively control surface development, these rights would obviously include any development of minerals. Quite clearly this would solve the pressing problems arising from surface working of coal, iron ore, gravel, sand, limestone and clay, where so much valuable agricultural land is being wasted through absence of adequate provision for restoration. It would permit the control, in the national interests, of the location of mineral workings of all types and open the way for the much-needed balanced planning of the use of the land of Britain.

L. Dudley Stamp.

THE ROYAL STATISTICAL SOCIETY

INDUSTRIAL AND AGRICULTURAL RESEARCH SECTION

The Council of the Royal Statistical Society has decided that the Industrial and Agricultural Research Section, the activities of which were suspended at the outbreak of war, shall be reconstituted in the form of two separate sections—a Research Section and an Industrial Application Section.

From its inception in 1933, the Industrial and Agricultural Research Section met the needs of the growing number of workers interested in applying statistical methods to industry and agriculture. It held regular meetings at which papers were read and discussed, and published the Supplement to the *Journal of the Royal Statistical Society*, which not only contained these papers with reports of the discussions, but also provided a medium for the publication of new developments in the field of applied statistics.

During the War, statistical methods were applied on a greatly increased scale ; in particular the need became apparent in industry for a common meeting ground where the experiences and difficulties arising in the practical application of statistical techniques could be discussed. On the initiative of Dr. B. P. Dudding, an informal Industrial Applications Group was formed in London to fulfil this need, and it was clear from the success attending the activities of the Group that there existed a considerable body of people who, though not necessarily professional statisticians or scientific workers, were very much interested in the practical aspects of the application of these new techniques to industry.

The Council of the Royal Statistical Society feels that the two distinct needs which are now evident will be catered for more adequately by the reorganization which has been effected. The Research Section will be concerned with the theory of statistics and statistical methods and with the development of new applications, while the Industrial Applications Section covers the practical application of statistical technique to industrial research, development, and manufacture, including inspection.

The Research Section, which will meet in London, proposes to hold four meetings during the coming session. Papers read at these meetings will be published in the Supplement to the Society's *Journal*, together with reports of the discussions. Details of the meetings will be announced in *Nature* and other appropriate journals. Visitors who are not members of the Section will be welcome.

The Industrial Applications Section is organized in local groups. In London, Birmingham and Sheffield, groups are already in existence, and the formation of groups at a number of other centres is under consideration. Discussions at group meetings will not in general be published, but should the local group committee consider certain papers to be of sufficient importance, their publication and method of distribution will be considered. Meetings of the groups will be announced in the appropriate journals.

The Supplement to the Society's *Journal* is edited by the Committee of the Research Section under direction from the Council of the Society. It is hoped that, in addition to publishing papers read before the Research Section, it will become a medium for the publication of research work on topics of general interest to statisticians. Such papers need not necessarily be theoretical or mathematical but should expound or illustrate some new development in statistical methodology. At present, papers of this nature are often published in journals devoted to special branches of science and not always readily accessible to workers in other fields.

Membership of either or both Sections is open to fellows of the Society free of charge and to non-fellows who are approved by the appropriate Section Committee, on payment of an annual subscription of ten shillings (for each Section). The Supplement to the *Journal* will be published twice yearly. It will be available to fellows of the Society free of charge and to members of the Sections at reduced rates. Further information may be obtained from the Assistant Secretary, Royal Statistical Society, 4 Portugal Street, London, W.C.2.

RESEARCH WORK AT THE MILLPORT MARINE LABORATORY*

THIS series of annual reports recently issued by the Scottish Marine Biological Association, covering as they do the war years 1939–44, are of great interest. Not only has the work been well maintained, but also the new wing, representing a considerable extension of the laboratory buildings, opened in June 1939, has been in general use. The staff, in spite of several members being absent on war service, has been extremely active and, in addition, workers from outside have added to the programme in various ways. This has been chiefly on the economic side, but ecological and faunistic work has still continued.

Dr. Orr's analysis of the various marine organisms with regard to their nutritive value, based on two hundred different species, including molluscs, crustaceans, fishes, cœlenterates, echinoderms and worms, shows that molluscs, crustaceans, fishes and worms are of high food value, echinoderms and cœlenterates low. The results have been tabulated. His more recent work has been chiefly an investigation of seaweeds with special attention to those likely to provide substitutes for Japanese agar. This research, later in collaboration with Dr. S. Marshall and throughout in close touch with representatives of the Ministries of Supply and Health, resulted in a satisfactory agar substitute being found in the red alga, *Gigartina stellatus*, which is now being used on a commercial scale. A survey of algæ is also being carried out.

Dr. S. Marshall, who in the early part of the period was occupied with the life-histories of certain copepods, besides this agar work, is, together with Dr.
and Dr. F. Gross and J. E. G. Raymont, of the Univ
sity of Edinburgh, taking part in an interesting expe
ment in Loch Sween and its small arm Loch Craigl
by fertilizing the water by the addition of nutri
salts and investigating the effect on the growth of
phyto- and zoo-plankton, and of the fish introduc
An account of this was given in *Nature*[1]. Latest repo
show that the added nutrients were rapidly absor
and an increase in the size of the fish was in ma
cases large.

The question as to the value of marine plankton
food for land animals was raised by Sir John Grah
Kerr in 1941, and Prof. A. C. Hardy of Aberde
with the approval of the Agricultural Research Coun
took the matter up and devised experiments in
operation with the Millport Station, primarily to se
plankton could be obtained in sufficient quantities
be used to form an addition to protein meal for anin
stock and poultry. Good samples of *Calanus* m
were prepared, but the results during the three ye
did not yield the hoped-for practical results, althou
Prof. Hardy regards it as a speculative investigat
which was well worth trying as a possible additio
source of protein in war-time.

In 1941, Dr. J. E. Harris, working under the Mar
Corrosion Sub-Committee of the Iron and St
Institute, began his researches at Millport on proble
connected with the marine fouling of metals. T
work has increased considerably and several assista
are now working at the various subjects, including t
colonization of the experimental rafts with plant a
animal growth. Much valuable information has be
obtained in connexion with these researches, t
technical side of which will be published in the repo
of the Marine Corrosion Sub-Committee. On t
biological side, among other points of interest, a
K. A. Pyefinch's work on the barnacle larvæ and I
M. Mare's on the succession of algæ and on the p
played by the bacterial slimes in the development
fouling growth.

Experiments on prawn trawling and on the p
duction of seaweed meal were also made, and besid
the work of direct economic importance ecologi
studies have continued, especially in Kames Bay,
Dr. A. C. Stephen and others, including the mollusc
and crustacean fauna, the microfauna of the intertic
sands, and insect larvæ of the shore.

The food of the shag was investigated by A.
Hadow and W. H. R. Lumby, who show close agre
ment with Steven's[2] observations, the bird being
little economic importance.

INDIAN PLYWOOD FOR TEA CHESTS

THE long stretch of country situated at the fo
of the eastern Himalaya is occupied by a su
cession of tea gardens which extend up into the out
hills to some 5,000 ft. or so elevation on the we
Since the introduction of the growth of tea into t
region, the necessary tea box or chest for packi
and exporting the tea has been something of a proble
with a varied history. In the supply of those garde
situated in Assam, saw mills were erected in Assa
many years ago, but most of the chests required ca

as imports from Europe in the form of shooks, tens and metal fittings, put together to form the st on the spot.

his century has witnessed the advent of plywood revolutionized the construction of the tea chests. *Indian Forest Records* (New Series: Utilisation, . 3, No. 4, Forest Research Institute, Dehra Dun, 5), Mr. V. D. Limaye deals with "The Testing of ian Plywood Tea Chests" with the object of estab- ing a standard type. With this objective in view, e different types of plywood tea chests were sub- ted to systematic scientific tests at the Timber ting Laboratory, with the view of establishing a ndard tea chest of Indian make, comparable with best of foreign makes. In India, plywood tea sts are manufactured from various timbers such hollock (*Terminalia myriocarpa*), hollong (*Diptero- pus macrocarpus*), mango (*Mangifera indica*), ul (*Bombax malabaricum*), pali, and others. llock is the main source of supply. It grows in forests of Assam.

n the past, boxes of all these timbers have been jected to systematic research at Dehra Dun. The ies of exhaustive tests here described was carried on nine different types of tea chests, known as 'O', 'S' and 'M' types made chiefly of hollock ber with the view of analysing their comparative rits, and establishing a standard type of Indian wood tea chest comparable with the best foreign kes. It would appear that this object has been filled and that in this respect India at last can be nsidered as no longer dependent on imports. Boxes each of the nine types, totalling in all 210, and presentative of the average quality produced by e mill, were supplied in shook form by the Assam w Mills. The most common size of box, namely, in. × 19 in. × 24 in., was chosen for the tests. In ch of the 'O' and 'S' types, boxes of sizes 14 in. × in. × 14 in., 16 in. × 16 in. × 16 in., 18 in. × in. × 18 in., 18 in. × 12 in. × 18 in. were tested, e thickness of the veneers varying. In the 'O' type e plywood was all hollock. In the 'S' type the tside ply is of hollong (*Dipterocarpus macrocarpus*). the 'M' type the outer ply is of semul. Boxes de with the side panels with the grain vertical are e strongest.

Summarizing the research work the following sults are given: The 'O', 14 in. × 14 in. × 14 in., d 'S', 14 in. × 14 in. × 14 in., types of plywood -chest are found to be very much stronger than e average of the best five makes of imported birch -chests, taken as the datum for comparison. By ducing the thickness of plywood to 3/16 in., it has en found that the cost of a tea-chest can be reduced, ing to economy in timber, without sacrificing the ength required. 18 in. × 12 in. × 18 in. type and in. × 16 in. × 16 in. type are both comparable to e datum birch tea-chests; but the 18 in. × 12 in. 18 in. type is found to be slightly stronger than e 16 in. × 16 in. × 16 in. type, probably due to a re balanced construction of plywood. The tea- est of 'O', 18 in. × 12 in. × 18 in. type, is, there- re, recommended as a standard, if making veneers two different thicknesses is not considered a great sadvantage from the manufacturer's point of view. 18 in. × 12 in. × 18 in. type is not considered nvenient, then 16 in. × 16 in. × 16 in. type, which the next best, can be established as the standard. ere is no difference of any practical importance tween the 'O' and 'S' types so far as strength is ncerned.

JOHN INNES HORTICULTURAL INSTITUTION

THERE is nothing merely formal or perfunctory, and much that is challenging, in the thirty-fifth annual report, for 1944, of the John Innes Horticultural Institution (from the Institution, Mostyn Road, Merton Park, London, S.W.19. 1945). Dr. C. D. Darlington, director of the Institution, has recently enunciated the hypothesis that "viruses of specific types can be created by grafting particular pairs of individuals". This is based on M. B. Crane's experiments on grafting the apple variety, Lord Lambourne, with other varieties. Lambourne may then become infected with two abnormalities—'rubbery wood' and 'chat fruit'—deemed to be viruses. From the evidence presented in the report, it would seem that such infection could be explained by the assumption that Lambourne is completely susceptible to the two viruses, for which most apple varieties are symptomless carriers. The assumption that viruses are 'created' by the graft union seems at least a little ahead of the facts.

Mr. Crane and Dr. Lewis make the interesting suggestion of raising hybrid raspberries from seed, in order to eliminate virus from the initial stock. Preliminary experiments show satisfactory yields from hybrids, but many facets of the problem require consideration before hybrid seedling production can be regarded as a commercial proposition.

Dr. P. T. Thomas has found that 'bolters' in the potato crop possess an extra chromosome fragment which may presumably account for their premature flowering. Statistical technique has been applied by Dr. K. Mather to the analysis of behaviour and organization of polygenes. This provides more exact equipment for the plant breeder; and makes it possible to predict minimal selective limits, to relate the actual number of genes to their observed expression, and to determine whether hybrid vigour has reached the maximum.

The Institution has adopted the title, "Answers to Growers", for its first *Bulletin* (price 2*s*. 6*d*. from the Institution). Growers appear to have left the Institution in no doubt of their needs and, if their questions are such as to epitomize the work of the John Innes at present, that selection only allows of more factual and experimental answers. The grower is told that hoeing is of value for weed control rather than for moisture conservation; that composting tomato haulms does not destroy any virus they may carry; that the ultimate behaviour of his plants depends a good deal upon the character of the compost used for raising seedlings. Questions about the practical culture of sweet corn are answered. The particular and complex methods of hybrid seed production of this crop by top-crosses, double- and three-way crosses, and by synthetic varieties, are explained. The question, 'What are the best plums to grow?', is answered by stating general principles—correct interplanting of dessert kinds (which are self- and cross-incompatible), the separation of high-nectar varieties from those with low nectar, and the choice of frost-free sites, as plums flower early in the season. Some varieties of apple are shown to resist attack by red spider.

The *Bulletin* has achieved the right practical tone; it is well produced, with a general series of photographs of experiments at the Institute, and the identity of the contributors is but thinly veiled by their initials.

FORTHCOMING EVENTS

Monday, December 3

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C 2), at 1.45 p.m —Dr. F. C. Bawden : "Virus Diseases of Plants", 3. "The Nature of Viruses" (Cantor Lectures).

Farmers' Club (at the Royal Empire Society, Craven Street, Strand, London, W C 2), at 2 30 p m —One Hundred and Third Annual Meeting. Dr. S. J. Wright : "The Next Phase in Agricultural Mechanisation".

Society of Engineers (at the Geological Society, Burlington House, Piccadilly, London, W 1), at 5 p.m.—Dr H. G. Taylor : "Earthing" (illustrated by Film and Lantern Slides)

Society of Chemical Industry (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6.15 p.m.—Mr. W. G Atkins : "Jute and the Chemical Industry" ; Dr. A. J. Turner : "The Properties and Uses of Flax".

Tuesday, December 4

British Society of International Bibliography (at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment; London, W.C.2), at 2.30 p.m.—Dr. R. T. W. Reynolds and Mr. W. A. Silvester : "Plastics, their Nomenclature and Classification" ; Mr. A E. Tooke : "The Information Bureau of the Electrical Research Association".

Zoological Society of London (at Regent's Park, London, N.W.8), at 5 p.m.—Scientific Papers

Royal Institution (at 21 Albemarle Street, London, W.1), at 5 15 p.m —Sir Henry Dale, O.M , Pres.R.S. : "Recent Developments in Chemical Therapeutics", (i) "The Beginning—Dyes, Arsenicals, Antimonials, etc.".

Royal Statistical Society, Research Section (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.15 p m —Mr. G. A. Barnard . "Sequential Tests in Industrial Statistics".

Royal Anthropological Institute (at 21 Bedford Square, London, W C.1), at 5.30 p.m.—Rev. H. St. John Evans : "Anthropology and the Missionary".

Wednesday, December 5

Royal Society of Arts (at John Adam Street, Adelphi, London. W.C 2), at 1.45 p m.—Dr. C. F. Goodeve, F.R S. : "The Defeat of the Magnetic Mine".

Geological Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. Leslie Rowsell Moore · "On the Spores of some Carboniferous Plants".

Institution of Electrical Engineers, Radio Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. F. C. McLean and Mr. F. D. Bolt : "The Design of Radio-Frequency Transmission Lines and Switchgear for Medium-Wave and Short-Wave Broadcasting Systems".

Society of Chemical Industry (Joint meeting of the Food Group with the Society of Public Analysts and other Analytical Chemists, at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 6 15 p.m.—"New Routine Tests and their Application in Modern Food Industry". (1) Dr. A. J. Amos . "New Routine Tests in examining Wheaten Products" ; (2) Dr. H. G. Davis : "New Routine Tests in the Dairy Industry" ; (3) Dr. F H. Banfield and Mr. J. C. Morpeth . "Some Newer Methods of determining Meat in Meat Products" ; (4) Mr. D. W. Grover : "Physical and Chemical Methods for Moisture Determination".

Society for Visiting Scientists (at 5 Old Burlington Street, London, W.1), at 7 30 p.m.—Discussion on "Science in India and the Colonies" (Speakers : Dr. S. Siddiqui, Dr. J. L. Simonsen, F.R S., Dr. E. B. Worthington and Major-General Sir John Taylor, C.I.E.).

Thursday, December 6

Manchester Joint Research Council (in the Whitworth Hall, The University, Manchester), at 11.30 a.m —Sir John Anderson, G.C.B. : "Research in relation to Reconstruction".

Physical Society (in the Lecture Theatre, Science Museum, Exhibition Road, London, S.W.7), at 5 p.m.—Dr. John A. Fleming : "Geomagnetic Secular Variations and Surveys" (Third Charles Chree Address). (Fellows of the Royal Astronomical Society and the Royal Meteorological Society are cordially invited.)

Royal Institution (at 21 Albemarle Street, London, W.1), at 5 15 p.m.—Sir James Jeans, O.M , F.R S. : "Physical Astronomy", (ii) "The Hot Matter of the Stars".

Institution of Electrical Engineers (at Savoy Place, Victoria Embankment, London, W.C.2), at 5 30 p.m.—Mr. R. H. Coates and Mr. B. C. Pyle · "The Operation of Large Turbo-Alternators to reduce Rotor-Winding Deformation".

Society of Chemical Industry (joint meeting of the Bristol Section of the Chemical Engineering Group and the Institution of Chemical Engineers, in the University Chemical Department, Woodland Road, Bristol), at 5.30 p.m —Mr. Stanley Robson : "Chemistry, Metallurgy and Empire" (First Robert Horne Memorial Lecture).

British Psychological Society (at Bedford College, Regent's Park, London, N.W.1), at 7.30 p.m.—Mr. W R. Bion : "Some Basic Considerations in the Dynamics of the Group" ; Mr. J. D. Sutherland : "Some Sociatric Lessons from Officer Selection".

Friday, December 7

Royal Institution (at 21 Albemarle Street, London, W.1), at 5.15 p.m.—Air Commodore F. Whittle . "The Advent of the Aircraft Gas Turbine".

Geologists' Association (at the Geological Society of London, Burlington House, Piccadilly, London, W.1), at 6 p.m.—Dr. A. J. Bull : "Terrestrial Heat and Earth Movements".

Saturday, December 8

Biochemical Society (in the Bearsted Theatre, London Hospl Whitechapel Road, London, E.1), at 2 15 p.m.—Scientific Papers Demonstrations.

Friday, December 7—Saturday, December 8

British Association for the Advancement of Science, Divis for the Social and International Relations of Science (at London School of Hygiene and Tropical Medicine, Keppel Str London, W.C 1).—Conference on "Scientific Research and Indust Planning".

Friday, December 7

At 10.15 a.m.—"Fundamental Research in relation to the Co munity" (Speakers : Dr. M. Polanyi, F.R.S , Prof J. W. Mun Prof. C. D. Ellis, F R.S., Prof. A. G. Tansley, F.R.S., Dr. C. D. Darli ton, F.R.S.).

At 2.15 p m —"Planned Research". (Speakers : Sir Edw Appleton, K.C.B., F.R.S., Dr. C. F. Goodeve, F.R.S., Dr. E. Armstrong, F.R.S., Sir William Larke, K.B.E , Dr. P. Dunsheat

Saturday, December 8

At 10 15 a.m.—"Economic Aspects of Research" (Speakers : P P. Sargant Florence, Mr. F. E. Smith, Prof. M. L. E. Oliphant, F.R.

At 2.15 p.m.—"The Human Factor". (Speakers : Sir Art Fleming, Dr. C. P. Snow, Mr. J. Kendall, Prof. J. D. Bernal, F.R. Mr. J. A Lauwerys.)

APPOINTMENTS VACANT

Applications are invited for the following appointments on before the dates mentioned :

Assistant Agricultural Organizer to the Holland Cour Council—The Principal, Agricultural Institute and Experimen Station, Kirton, Boston, Lincs. (December 8).

Assistant Advisory Officer in Market Gardening to the Ke Education Committee—The County Agricultural Organizer, Brunswi House, Buckland Hill, Maidstone (December 8).

Chief Engineer and Manager to take charge of operations Electricity Supply Division of Department of Industries and Labo Government of Burma—The Ministry of Labour and National Servi Appointments Department, Technical and Scientific Register, Roo 670, York House, Kingsway, London, W.C.2, quoting D.1555. (December 10).

Lecturer in Biology (Honours Graduate, with Physiology subsidiary subject)—The Clerk to the Governors, South-East Ess Technical College and School of Art, Longbridge Road, Dagenha (December 10).

Production Chemist (Degree standard, with experience in sup vision of manufacture and packing of food or domestic products) large manufacturing firm (household products) in West London- The Ministry of Labour and National Service, Appointments Depa ment, Technical and Scientific Register, Room 670, York Hous Kingsway, London, W.C.2, quoting F.5123 XA (December 11).

Mechanical Engineer (University degree or A.M.I Mech.E. equivalent, with practical training and experience in design of sen heavy engineering plant, preferably hydraulic and oil-field equipmen by old-established contracting and manufacturing company in Lond area—The Ministry of Labour and National Service, Appointmen Department, Technical and Scientific Register, Room 670, York Hous Kingsway, London, W.C.2, quoting C.2950.XA (December 11).

Principal of the Peterborough Technical College—The Ch Education Officer, Education Offices, Town Hall, Peterborou (December 15)

Senior Technician in the Department of Biochemistry—Pr H. Raistrick, F.R.S., London School of Hygiene and Tropical Medicin Keppel Street, London, W.C.1 (December 31).

Junior Lecturer in the Biology and Pharmacy Department- The Clerk and Treasurer, Dundee Institute of Art and Technolog Bell Street, Dundee.

Laboratory Assistants—Grade I and Grade II for the Che istry Department, and Grade I for the Physiology Department- The Secretary, King's College of Household and Social Science, Camden Hill Road, London, W.8.

General Secretary—The Hon. Secretaries, Society of Chemi Industry, 56 Victoria Street, London, S.W.1.

Lecturer in Chemistry—The Principal, Leicester College Technology and Commerce, Leicester.

Lecturer (full-time) in Zoology and Biology—The Cle Northern Polytechnic, Holloway Road, London, N.7.

Laboratory Technician (male, Grade B), experienced in Hæmat logy and Biochemistry and in taking specimens of blood from patie —The Secretary, Harrogate and District General Hospital, Harroga

Lecturer in Mathematics in the Canterbury University Colle Christchurch, New Zealand—The Secretary, Universities Bureau the British Empire, c/o University College, Gower Street, Londo W.C.1.

Visiting Lecturer in Psychology (temporary)—The Secreta King's College of Household and Social Science, c/o University Colle Leicester.

Lecturer in Psychology in the University of the Witwatersra Johannesburg—The Secretary, Universities Bureau of the Brit Empire, c/o University College, Gower Street, London, W.C.1.

Graduate Lecturer to teach Biology to at least Intermedi B.Sc. standard—The Principal, Norwich City College and Art Scho St. George Street, Norwich.

Graduate Assistant (full-time) in Biology (to First M.B. a Inter. Pharm. standard), and Physiology and Anatomy for rec nized pre-nursing classes, in the South Devon Technical Colle Torquay—The Education Officer, Lymington Road, Torquay

TECHNOLOGY AND ADMINISTRATION

MEMBERS of the present Government have already made several statements of their appreciation of the importance of both scientific and industrial research, and affirmed that the Government is no less determined than its predecessor to encourage and support its prosecution within industry, by the universities and by the Departments of State. That research is an essential factor in industrial efficiency is a lesson well learnt since the Balfour Committee published its series of reports in the decade after the First World War. The need for a great expansion in the nation's research effort is now unchallenged : the questions at issue are rather how best to utilize our available resources of men and material, and to provide the most effective means for expansion.

Research, however, is not the sole factor in industrial efficiency that calls for the fuller and wider use of trained minds. Mr. Herbert Morrison, Lord President of the Council, rightly remarked on November 6, in addressing a conference of industrial research associations, that scientific and technical help will be required on the administrative and production side as well as in research, in order that effective use may be made of the new processes and products which may come from research. This has been followed up by the appointment by the president of the Board of Trade of a committee under the chairmanship of Sir Clive Baillieu, president of the Federation of British Industries, to frame proposals for the formation of a British Institute of Management, to which the Government would contribute financial assistance.

The importance of management has been stressed in many recent reports on scientific and industrial research, such as those coming from the Parliamentary and Scientific Committee, the Association of Scientific Workers, the London Chamber of Commerce and other bodies, and is a main theme of two important reports which have just appeared.

The first of these, "University Education and Business", comes from a committee, under the chairmanship of Sir Will Spens, appointed by the Cambridge University Appointments Board*. This report was the outcome of an inquiry initiated in 1937 to consider how adequately the University of Cambridge was equipping students who intended to use the business world, and whether employers were using as well as possible men trained by the University. Admittedly it is based only on samples, for of three hundred firms to which a letter of inquiry was addressed, only one hundred and fourteen replied ; while, of some seventeen hundred Cambridge graduates known to be in business, only three hundred and twenty-six replied to a similar but differently worded letter. Members of the Committee also collected certain important facts and solicited the opinions of those having special knowledge. Moreover, the inquiry must be recognized as a definite attempt by the Cambridge University Appointments Board to fulfil functions laid down by Dr. C. P. Snow as necessary for university appointments boards, and by the Hankey Committee for the Appointments Department of the Ministry of Labour and National Service. The Committee has clearly done an admirable piece of work, and the report offers a prototype for inquiries which might be undertaken systematically by other university authorities.

---

* University Education and Business. Pp. viii+78. (London: Cambridge University Press, 1945.) 2s. 6d. net.

The report opens with the frank recognition of the far-reaching social changes which are taking place in the national life of Britain, and in particular the implications of our changed outlook on education. Educational changes are likely to increase the number of really able men who succeed in obtaining university education at the public expense, so that in the future the number of such men who have not been to a university will be considerably fewer. The process of selection by ability is taking place at all ages and educational levels, and will greatly affect the industrial population. The 'working parties' appointed by Sir Stafford Cripps will not need to probe deeply into the measures required to increase the efficiency of the industries they are investigating to discover the great importance of recruiting the right type of industrial leader. This question is as important from the point of view of eliminating social and industrial friction as of industrial advance. Industry needs minds competent both to appraise the human factors in a situation and quick to appreciate the possibilities of technical innovation. Its leading positions more and more must be filled by men whose minds by habit and training are strategic rather than tactical, who are accustomed to verify ideas and opinions by a study of facts and results, and to take long-term rather than short-term views of costs and advantages.

Apart from this, the gradual raising of the educational standard and cultural outlook of industrial and clerical workers in itself will accentuate the demand for a higher standard of industrial leaders. Business will require an adequate supply of the ablest minds, and since these will in the future be drawn for the most part from the universities, it is important that university education should be such as to fit them for their part, as technicians, as managers or as directors. In regard to one university, the report confirms the widely held opinion that the intellectual level of men entering business is, on the whole, not so high as that of men entering certain other occupations. Only about one third of the men who left Cambridge in 1937 and 1938 went into commerce or industry on the administrative or scientific side; and although only one half of this number of men took up administrative or research posts outside business, this sixth included two thirds of all the Cambridge men who gained first-class honours in those years. Judged by this definition, those entering business included less than one fifth of the 'best brains'. Over the two years, only the Forces had a lower percentage than business, excluding its scientific side, among their entry.

The report considers in detail some of the factors affecting the recruitment of university men for business and their employment when recruited, and in this the opinions of both employers and graduat were very helpful. The latter were more critical, b the former were for the most part very full and ca fully thought out, sometimes the result of conferenc of executives. Both sets of replies showed clea that the university man has an important part play in the business world, and endorse the t fundamental assumptions which underlie the repor first, industry, in its widest sense, plays a mo important part in the social life of a modern co munity; and secondly, business provides an opp tunity for the highest form of social service for ma of the ablest people in the country.

The report rightly points out that universi residence as such is not necessarily an advantage business; it is only an advantage to the man who able to assimilate what is offered at the universi and to benefit from it. Some undergraduates wou undoubtedly make better use of their time at t university if their minds were more mature and h been fortified by some experience of practical li University education, the Committee suggests, probably of most use to those who are sufficient mature to have a sense of values, but not so matu as to find difficulty in appreciating new values; a what the Committee has to say on this question the type of university man wanted in business has profound bearing on the absorption into industry a commerce of men and women released from t Forces whose attainments and character qualify the for employment which would lead to administrati and executive posts.

The observations of the Cambridge Committ appear to be more fundamental than those to found in the report on Training for Business A ministration made by the committee appointed by t Minister of Labour and National Service last Februa under Sir Frank Newsom-Smith as chairman to co sider the latter problem and to make recommend tions for suitable courses of training. That report not concerned with men who may wish to acqu professional qualifications, as for example in accou ancy or law, as a preliminary to entering the busin world, and it also excludes those who may wish graduate or take a postgraduate course in busin administration, and for the same reason—th educational facilities and, if necessary, financ assistance are already available for both these class While this Committee may well be right in co sidering that the ex-Service men with whom they a concerned will want to obtain employment as quic as possible after their release from the Forces, it difficult to avoid the conclusion that the Commit has taken a narrow and short-term view of t problem, and that the long-term and national po of view has received insufficient attention.

The problem was considered almost entirely from t point of view of the ex-Service man and the employ and for the most part the Committee's recommen tions for provision of a course of basic general traini in business administration lasting about three mont full-time, or longer part-time, and given at techni and commercial colleges before or after engagem by an employer, with financial assistance availa der the Further Education and Training Scheme, e of passing, rather than permanent, importance.

The main exception to this is a suggestion, falling yond the Committee's terms of reference, for an terdepartmental committee of representatives of e Ministry of Labour and National Service and the ducation and Service Departments to supervise the rangements and co-ordinate schemes of post-release aining with training given while men are still in the rvices. Such a committee could usefully supplement the work which it is proposed the university pointments boards or the Appointments Department of the Ministry of Labour should do, and may ell assist in the education of industry and business this matter.

If business is to attract a sufficient proportion of e ablest men to ensure that wise leadership is always ailable, it will find itself in competition with other cupations, and the report of the Cambridge ppointments Board accordingly considers the use ade of the university men in business. Probably e strongest incentive determining choice of occupaon is a desire for responsibility. If a man has a ceptive mind and has lived for three years in an mosphere of ideas in close contact with men whose unction is to stimulate them, he will be anxious find an occupation providing an opportunity for e exercise of ideas. If he has not, he will be e type of graduate that employers are agreed ey do not want. Able graduates should not therere be recruited by firms unless there are obvious ositions of responsibility to which they can reasonbly look forward in the not too distant future.

The report makes the important point that the aining given to university men in business should e adapted to their stage of mental development, hich obviously differs from that of the schoolboy ntering business. Again, those being trained for anagement should know something of the special kills in each department of a firm and their relative ifficulty, and they should know a good deal about e interaction of departments ; and special stress is id upon the value of sympathetic sponsorship of an ppropriate senior member of the staff in helping the oung graduate to appreciate the purpose and method f his training, stimulate or curb ardour as occasion quires, and ensure that he gets a fair deal at the ands of executives under whom he will be working uring his tour of departments. Such handling will lso encourage that feeling of loyalty which firms ten say is one of the best features of university men business, and which is one of the most valuable fts a man can offer to an institution.

The Cambridge report also urges that a larger oportion of the higher administrative posts should e held by men with a scientific training, particularly manufacturing firms. It challenges the fundaental snobbery running through the whole social stem of Britain, which tends to regard those who al with organization and finance as superior to ose who deal with research and production ; and its assertion that the only way to make science operly available in the public service and business to insist that the technical expert be equal in status and pay to the non-technical administrator in every grade of promotion, the report is in line with the recommendations of the Barlow Committee on Scientific Staffs in Government Departments.

On the side of the University, the report makes a number of suggestions for strengthening its links with the world of business and industry and for improving the preparation of the graduate for that world ; these suggestions include the strengthening of the Appointments Board and the content of courses. All these observations, like those on the value of business experience before or during a university course, deserve the attention of other universities and appointment departments. Moreover, the whole report abounds in observations which are suggestive of ways and means by which firms could do much to eliminate the present weaknesses, and above all that tendency to regard technical posts as blind-alley occupations unless they lead to administrative posts in technical firms.

Another report recently issued is that of the Special Committee appointed, in April 1944 under Lord Eustace Percy as chairman, by the Minister of Education, Mr. R. A. Butler, to advise on the needs of higher technological education in England and Wales, with particular reference to the means for maintaining co-operation between universities and technical colleges (London : H.M. Stationery Office. 6*d*. net). The Committee's inquiries convinced it of the need for a standing organization, both to survey industry and to co-ordinate education. The evidence submitted concurred in the general view that the position of Great Britain as a leading industrial nation is being endangered by a failure to secure the fullest possible application of science to industry, and that this failure is partly due to deficiencies in education. In particular, the experience of war has shown that the greatest deficiency in British industry is the shortage of scientific men and technologists who can also administer and organize, and can apply the results of research to development. While recognizing that both educational institutions and industry may not have handled their material to the best advantage, the Committee concludes that industry and educational institutions training for industry are not getting their fair share of the national ability.

The Committee's suggestions for a campaign to increase the prestige of the technical professions and to arrest some of the present leakage of good brains from secondary schools at the age of sixteen include a continuance of the special State bursary system, both for universities and for technical colleges, with improved methods of selection, and the extension of the benefits of this system to candidates from industry as well as from secondary schools. It is urged that the whole question of scholarships for students of technology needs thorough reconsideration. Like the Nuffield College statement, the report challenges the adequacy and the dominance of evening classes for higher studies so exacting as those demanded of the modern engineer ; and in raising the whole question of adjustment between technical college and university courses, as parts of one coherent system of higher technical education, the report touches also on the question of the movement of postgraduate students, and the coherent planning of technological research in Britain, or rather of the institutions where it can be prosecuted with adequate facilities and resources.

The main outcome of this report is a scheme for the co-ordination of higher technological education by a National Council of Technology and a series of regional advisory councils throughout England and Wales; but one looks in vain for any clear conception of the relative functions of the universities and technical colleges. In spite of the emphasis laid on quality, there is little attention paid to the vital importance of research. Quantitatively, the Committee has only attempted to define the needs in respect of mechanical, electrical and civil engineering, and its pre-occupation with engineering may be partly responsible for the proposal, on what might appear inadequate grounds, for the selection of a strictly limited number of technical colleges—for engineering, up to six is suggested—in which there should be developed technological courses of a standard comparable with that of university degree courses.

The need for further co-ordination of the work of the technical colleges and the universities of Britain has been emphasized in other reports, and the Committee's proposals go some way to meet these criticisms that the existing provision for advanced technical education lacks form and system. The regional advisory councils it proposes would be concerned with the co-ordination of technological studies in universities, colleges of technology and other technical colleges of the region. As an essential part of the regional machinery it suggests also regional academic boards of technology, composed of the academic heads of universities and technical colleges and of members of their teaching staffs, and the consultation with industry which is an essential purpose of the whole regional organization should be conducted largely through this agency.

The regional machinery would have its national counterpart in a National Council of Technology at least partly representative of regional advisory councils and of the regional academic boards, but appointed by the Minister of Education at his discretion. This body would be responsible for considering the national aspects of regional policies, and for advising the Minister and the University Grants Committee; but no change is suggested in the administrative responsibilities of these two central authorities, nor any restriction of their freedom of communication with local education authorities and universities and with the regional bodies. The constitution of the regional academic boards is outlined in more detail, and it is to these boards that the Committee believes that the country must mainly look for advice on the steps necessary to meet the demand of industry for quality.

These proposals obviously should help to provide industry with more of the technical leaders it requires, though their bearing on the all-important question of quality is less apparent. The report estimates the requirements of the engineering industries for senior administrators, engineer scientific workers and development engineers and engineer managers at abo 3,000 each year, of whom upwards of half must drawn from the technical colleges, the limit of t output of the universities and university colleges England and Wales being put at 1,200. But it for some 350 of the trained engineers coming fro the technical colleges that the Committee propos to develop the special colleges and courses alread noted.

Two concluding recommendations of the Committee are, however, of more interest to this questio of providing industry with the quality of leadersh it requires. First, in regard to management studie the report recognizes that this body of knowledge ca be taught only by those who have a thorough practic and theoretical grasp of it, and comments on t poor quality of the present literature of the subje in Britain and the absence of the intellectual conte of a sound mental discipline. The report accordingl recommends that all students of technology, wheth at universities or colleges of technology, should introduced to these subjects during the final year two of their undergraduate course. It also recommends that at least one institution should be select as a centre for postgraduate study of industri administration. It should be the function of th centre to set standards in the teaching of the subje to systematize it as a mental discipline, to condu the necessary research, to develop the literature the subject and to train teachers for it. The repo also recommends that management studies shoul form a part of the courses of all technical colleg teaching for the national certificates and diplom and should form the subject of short or refresh courses organized jointly by teaching institutio and industry.

The second matter relates to the special needs teachers of technological subjects in universities an technical colleges. The only really satisfactory wa for such teachers to keep up to date in the industri technique of their particular subject is for the teach to return to industry for substantial periods. This a matter which might well be dealt with by t regional academic boards in collaboration with t industries in the region, while the National Coun of Technology might arrange for exchanges wi teaching institutions abroad. Something might a be done for teachers in the way of refresher cours of an academic character, while industry should prepared to release senior members of staff to gi advanced courses of lectures during the day. B the most effective remedy will probably be found the upward adjustment of the salary scales teachers and lecturers in the technical colleges a universities.

The first of these matters is clearly related to t proposals for an Administrative Staff College a nounced almost simultaneously with the publicati of the Percy Report. This new venture, initiat with the support of individuals and groups fro industry, local government, education, commerce a distribution—but not, seemingly, the Civil Service is intended to bring together able young men a women who have already mastered the arts ganization in their own departments, in a more tensive study of the science of administration in its ider applications. The College is not to be conrned with preliminary training, but is rather an periment which, if it is to succeed, must provide a eeting place of the administrative officers of both e public and the private services. It is a staff llege and not a training college, and is intended to e and to do something quite different from any ventual Civil Service college. Indeed its most aluable function may be to promote the closer nderstanding by the two types of administrators of ch other's problems.

In future, as in war-time, the industrial and the ublic administrator must work increasingly together, nd if friction and frustration are to be avoided in hatever changes may take place in the structure nd organization of industry, the public services or he machinery of Government, these two types of dministrator must understand the very different tuations in which they are placed and the different esponsibilities which they carry. The success of the enture will be judged by the measure in which it ssues in better practice directed to the fuller service f the public interest—the same criteria by which the uccess of that other experiment by the 'working arty' initiated by Sir Stafford Cripps will be judged. efore it can well start, however, two conditions have o be fulfilled, as Sir Hector Hetherington, himself ne of the court of governors, has pointed out. Staff f the right kind—experienced, lively, knowledgeble and skilled in the Socratic art—must be found; nd the student body must be sufficiently numerous and varied to achieve the fertilizing purpose of mutual riticism and stimulus. It is difficult to see that dequate numbers of students or sufficient variety will be secured without the participation of the Civil ervice; but there can be no question as to the mportance of experiment along such lines, so that ve may be able to secure both the closer integration f industry and business with the work of government nd the service of social needs, and to provide managers and administrators who are fully equipped o deal with the ever-increasing complexities of the ask of administration in the modern world.

ECOLOGY IN THE SERVICE OF MAN

Natural Principles of Land Use

By Edward H. Graham. Pp. xiii+274+32 plates. London, New York and Toronto: Oxford University Press, 1944.) 16*s*. net.

THE theme of this book is set out in its opening paragraph: "We live in an environment of many acets related not as single pieces but as a mosaic, the attern of which is not easily discerned at first glance. t must be seen in different lights before we appreciate ts full design and real worth". Disturbances of one f the pieces of the mosaic may have far-reaching ffects, yet directly man passed out of the hunting nd fruit-collecting stage he began to disturb the pattern, sometimes with unforeseen and disastrous results.

Clearly man must go on interfering with Nature, but he should at least know the consequences of his actions so that he may make them as innocuous as possible. It follows that land utilization must be planned and not haphazard. But a plan involves the detailed study of the region, the classification of its component parts and the study of their mutual inter-relations. Dr. Graham has amassed a great quantity of material much of which will be new to many English readers; he deals largely with American investigations. He shows that the inter-relations between plants or animals with individual factors of their environment can rarely be expressed in simple terms because of the far-reaching nature of their effects. Thus attempts to relate plant-growth with rainfall have succeeded only to a limited extent either in America or in Great Britain. On the other hand, the natural mosaic of any region is a faithful integration of the environmental conditions and so affords reliable guidance about its agricultural possibilities. Hence the need for a close survey which should not be confined to plants, but should also extend to animals, including insects; the soil; the topographical and climatic conditions. He instances the well-known fact that land, which in its natural state is covered with grass and other herbs, is naturally well suited to cereals, while some types of forest indicate suitability to fruit trees.

When natural grass or prairie land is used for grazing, no important change in the flora need be expected provided the grazing is light; but the change becomes very marked when it is too heavy, and deterioration of the herbage then sets in. The changes in any region follow a certain sequence so that the danger can be recognized before much harm has been done, and steps taken accordingly.

Some of the most interesting sections of the book deal with the chain of consequences following on man's disturbance of Nature's mosaic. As one would expect, the 'Dust Bowl', the termination of the soil erosion process, is fully dealt with, as also is the reverse process of rehabilitation. The results of introducing a new component to the mosaic cannot yet be predicted, nor is it clear why the new introduction sometimes romps away and multiplies at a tremendous rate, like rabbits in Australia or water hyacinth in Bengal, and sometimes dies out more or less gradually leaving no trace behind. The converse problem of eliminating one of the components of a natural community presents many interesting possibilities. In Utah, sweetened poisoned bran was set to control grasshoppers. It succeeded, but raised new troubles for apiarists, orchardists, soil conservers and others. Bees were killed, yields of honey went down, pollination was reduced, fruit yields fell, clover seeds did not set, and hence the plants failed to reproduce themselves; the soil cover suffered and soil erosion set in. So the tale goes rippling on, apparently *ad infinitum*, further proving

> "that thou canst not stir a flower
> without troubling of a star".

The author quotes with approval the work of M. A. C. Hinton on rats. The common rat of England was the black rat, which originated in the forests of India and Malaya and came to Britain at the time of the Norman Conquest or the Crusades; it can carry the plague pathogen and was responsible for the Black Death and the Plague of London. Then the brown rat came in from the plains of Asia. It gradually ousted the black rat from the level places and became the common rat in Britain. It has plenty of sins to its charge, but at least it does not carry plague. Before the War, however, the cellars of London were being made rat-proof, and so it found life difficult. On the other hand, flat roofs, sky-lights, cables, etc., were multiplying, and overhead London became a very suitable habitat for the black rat. So being safe from the brown rat, it was multiplying before the War and was becoming the common rat of London. Should plague break out it might become a menace. As Mr. Hinton says: "If you create a vacancy it is your own very difficult business to fill it".

The independent calculations of Fawcett and of Shantz indicate that something like 6–8 acres of cultivable land in the world per head of population are available to provide food and raw material. On present yields and practices this area barely suffices. Higher levels of production must be widely attained, and this will mean more and more interference with the mosaic of Nature.

The book will serve a useful purpose in setting out the principles on which rational land utilization must be based if unforeseen and undesirable effects are to be avoided. E. JOHN RUSSELL.

PRINCIPLES OF EDUCATION

Education

Its Data and First Principles. By Sir Percy Nunn. Third edition, revised, and in part rewritten. Pp. 283. (London: Edward Arnold and Co., 1945.) 7*s*. 6*d*. net.

OF all the late Sir Percy Nunn's numerous and varied writings, this book is the acknowledged masterpiece. Within a comparatively short compass, it reveals his educational doctrine and sets forth the powerful arguments by which he supported it. In a sense it is a summary of his life's work. Published in 1920, and reprinted many times during the ensuing ten years, it reached its second and revised edition in 1930. For this third and, as the sad event has proved, final edition, the author completed the revision himself, and sent the result to England from his enforced exile in Madeira a few weeks before his lamented death.

The previous editions contained fifteen chapters, all of which have been thoroughly revised by him, considerably expanded, and in some places rewritten. A new chapter has been added. The recent remodelling of our school system had made the fundamental problems of education the subject of unprecedented debate and had made it desirable to treat some old questions more fully, and to give new questions their place in the argument of the book. As the author emphatically declared, however, the central thesis of the book remains unchanged; it maintains as firmly as ever that "the primary aim of all educational effort should be to help boys and girls to achieve the highest degree of individual development of which they are capable". It is good to know that the author lived long enough to see with satisfaction that a widespread acceptance of this idea was a striking, and bade fair to be a permanent, by-product of the war years.

The new chapter to which reference was made above is the tenth in this edition and is entitled "Mental Development". The author's eminent work in the teaching of mathematics enabled him to p the whole matter so simply that any intellige person can follow the argument, provided he or s is both able and willing to devote the necessary tir and trouble. One is left, however, with a lurki suspicion that many teachers and administrators w regard this matter as one for the experts, who are no means in close agreement even upon fundament issues. The non-experts will continue to give respe ful attention to the results of 'intelligence test but they will also continue to believe that wh scientific analysis has said its last word, they mu turn to the whole personality, the living child who immediate future is being decided. Fortunately, t Act of 1944 puts an end to the absurd practice making irrevocable decisions about children at t tender age of ten. T. RAYMONT.

BOTANY IN LATIN AMERICA

Plants and Plant Science in Latin America

Edited by Frans Verdoorn. (A New Series of Pla Science Books, Vol. 16.) Pp. xl+384 (38 plates (Waltham, Mass.: Chronica Botanica Co.; Londo Wm. Dawson and Sons, Ltd., 1945.) 6 dollars.

THIS volume contains a great number of articl dealing with the botany and geology of Sou America. The botanical contributions cover a wi field including taxonomy, ecology, plant geograph economic botany, cytology and genetics. There a also accounts of rubber culture, fibre plants and sketch of the geology of the Antilles and a bri account of the general geological features of Sout America.

The editor has enlisted the aid of eighty-five co tributors from South America, the United States an a few from Europe. The book is divided into tw parts, the first of which deals with problems tropical agriculture, phytogeography of the continen economic plants, with a special supplement on pla breeding, genetics and cytology. The second pa consists of revised articles which have appeared i *Chronica Botanica*, chiefly on the floras of differe regions. Many of these articles are of great interes such as "The Falkland Islands" by Dr. Scottsber and "The Vegetation of Ecuador" by Dr. Svenso to mention only two out of more than a dozen o phytogeography. A geological sketch of Sout America is given by Dr. Darrah.

It is impossible in the space of a review to giv any detailed impression of this extensive and vari subject-matter; the index alone covers fourtee pages. The arrangement of the articles does no appear to follow any definite plan, so that referenc to any subject is not easy; even the longer contribu tions are restricted to a few pages and merely r present summaries of extensive subjects. Scatter between these are a number of short notes regardin some regional aspect of agriculture or economi botany. A short bibliography to some of the longe articles is a useful feature.

A number of plates taken from various source embellish the text, and many of the contributio are illustrated by outline maps.

While little detailed information can be obtain from many of the articles owing to their short length this volume can be recommended as a most valuabl general reference book to all botanical and alli subjects in Latin America.

THE MISSION OF SCIENCE*

By Sir HENRY DALE, O.M., G.B.E., F.R.S.

THE scientific men of the world now have before them the task of readjustment which, we may hope, will mean the whole-hearted devotion of the vailable resources of scientific research and development to their proper and beneficent uses. It has become a commonplace that the urgent needs of war have greatly accelerated discoveries and inventions which will now promote the advancement of science and its applications in peace. Some of these scientific words and spears will be thus immediately applicable as peaceful implements, or with only a minimum of beating and bending—radar, for example, to the safety of transport by sea and air, and all the new wealth of chemotherapeutic agents and insecticides o peace-time hygiene and agriculture. There will certainly be many others of a less direct and obvious kind—discoveries and developments arising as side-issues from the urgent uses of science in war, but capable now of applications which may open new possibilities of scientific advance for its own sake, or for a whole range of peaceful purposes. The Royal Society has recently agreed to collaborate with the Service Departments concerned, in setting up committees to organize such peaceful uses of the special facilities for purely scientific observation and experiment as are presented by Service flying, including aerial photography, by the voyages undertaken by the ships and officers of the Royal Navy in the course of their normal duties, and by the large surplus of explosives—of the pre-atomic type, be it understood —which a great war leaves in hand.

Let me make brief mention, by way of another example, of an unexpected gift to science, arising as a curious side-issue from the large-scale application in war of knowledge which science had provided. Some thirty years ago my former colleague, Dr. Charles Todd, published in the *Proceedings of the Royal Society* two papers dealing with the antigenic individuality observed, even within the limits of a single breed of chickens, when the red blood corpuscles of one bird are injected into another. This was an observation, one might think, of an interest purely theoretical, though great; but the widespread application of blood transfusion during the War, to replace blood lost by the wounded, civilians now as well as warriors, has given to phenomena of this type a practical importance. Apart from the familiar natural incompatibilities, due to the known human blood groups, it was found necessary to be alert for reactions in persons who, having had an earlier transfusion, might have acquired, by an immunity reaction, a new incompatibility to the donor's red blood corpuscles. The case of such reactions hitherto most completely studied concerns an antigenic factor which Landsteiner and his colleagues had discovered, early in the War, in the red corpuscles of the Rhesus monkey, and had accordingly termed *Rh*. This factor they found to be present, as a Mendelian dominant, in the corpuscles of most white people, but absent from those of a minority. So, in the slang of the subject, about 85 per cent of people of the white races are '*Rh*-positive', while 15 per cent are '*Rh*-negative'. Now it appears that the blood serum of an *Rh*-negative person, if he receives a transfusion of *Rh*-positive blood, acquires immune substances destructive to the 'positive' red corpuscles. In consequence, he suffers a dangerous reaction if given a second, similar transfusion. This observation has brought to light the much more important fact that, when an *Rh*-negative woman, whose husband is *Rh*-positive, becomes pregnant by him of an *Rh*-positive child, her serum is liable therewith to acquire, and to transmit through the placenta, an antibody destructive of the child's red corpuscles, so that the offspring of such a union are prone to a high rate of mortality, before or soon after birth. Whether those who survive the infantile malady thus produced show a greater liability to other hereditary defects, or whether deleterious maternal antibodies of this type can be formed in relation to other kinds of cells than the red blood corpuscles, are matters on which investigation must be awaited.

I mention the matter as an example of the gleanings which peaceful science may expect from fields of knowledge which war has been tilling and reaping. Unless I am mistaken, the widespread use of blood transfusion has thus been largely responsible for enabling human genetics now to explore a new category of congenital defects, due, not to the coincident presence of a detrimental gene in both parents, but to the possession by a father of one which is harmless, unless it excites an immunity response in a mother who lacks it.

Whether by following in new directions clues which have thus been discovered under the stimulus of war, or by resumption of researches which the War interrupted, it is clearly a matter of urgent importance that our scientific activities should now, as rapidly and as smoothly as possible, reacquire the character proper to peace. There are directions in which official action can accelerate a process of such outstanding significance to the position which our nation will be able to achieve and to hold in a world civilization, now so clearly entering its scientific era. We need our leaders and teachers in science back in the universities, and the students whom they can inspire and train, as rapidly as these can be released from war-time duty and service.

A number of our leading men of science have learned much from war-time experience of organization and team-work in research, and have been freely devoting great abilities to planning and to securing proper conditions for researches by others. It is unlikely that the debt of the nation and of its allies to the work of many of these will ever be fully known, beyond the limits of certain circles. The experience of these men should help them still to serve the nation in peace, by counsel and by advocacy, when the needs of scientific reconstruction demand these.

I venture to hope, however, that there will be no such demands on the time and the energies of those who should now be our leaders in research, as to keep them away from their benches and their studies, and to deprive of their inspiration the younger men who should now be their pupils and collaborators. When the world emerged from the War of 1914–18, the scientific men who in Britain and other countries were then at the height of their powers for research, who, in Newton's fine phrase about himself, were 'in the prime of their age for invention', were back in their laboratories with little delay. As a result, even in the two decades of uneasy armistice which followed, curtailed at both ends by the confusion of recovery from one war and the gathering menace of another, research for the normal purposes of peace was resumed with an astonishing promptitude, and the advance of knowledge surged forward with an imposing acceleration. Almost any man of science who can cast his mind back to the state of knowledge in his own special subject in 1919, and compare it with that which had been reached in 1939, must be impressed by the transformation. To mention an example which cannot be far, at the moment, from anyone's thoughts, consider the revolutionary changes made, between the wars, in our whole conception of the material universe, by new theories of atomic structure, with new apparatus of mathematics to deal with them, by the experimental attack on the atomic nucleus leading to transmutation of elements and, still before war's dark curtain fell again, clear evidence of atomic fission, with the release of atomic energy. As one other example, who would have predicted in 1919 that, of the vitamins and hormones then known and differentiated only by the effects of their withdrawal and replacement, imposing ranges would have been isolated, identified and made by artificial synthesis before 1939 ? Now that we are emerging from another war, into what, if we men of science can do anything to prevent it, will not be just another precarious interlude before a worse disaster, we must try to ensure that the free advancement of natural knowledge, which this Society exists to promote, is able to claim again, with as little delay as possible, the full service of its natural leaders.

---

* From the anniversary address to the Royal Society, delivered on November 30.

Another condition of the revival of scientific activity for the normal purposes of peace, seen clearly by our predecessors in 1919, was a rapid reconstruction of the international community of science. Before there had been time for the full attainment of their aim, the forces of cleavage had again begun to operate ; but, as soon as it became possible once again to think of rebuilding what another war had broken, it was the first duty of the Royal Society to ensure that use was made of all that was of proved value in the framework of international collaboration which had been constructed between the wars. Past officers of the Royal Society, especially Sir Arthur Schuster and Sir Henry Lyons, had taken prominent parts in the foundation and development of this organ of international collaboration. Our foreign secretary, Sir Henry Tizard, now coming to the end of his term of office, was early at work preparing for its revival with the chairmen of the British national committees, in consultation with its present general secretary, Prof. F. J. M. Stratton, and with such representative scientific men of other countries as were accessible. Their aim was to review the past achievements and potential value of this system of the international scientific unions, and the possible need for its extension or modification in certain directions. The Council's reports record the progress which has been made.

While, however, the Royal Society has had a special responsibility for our national participation in this existing system, it has always welcomed any opportunity of the fullest and most friendly collaboration with any other agency for the promotion of international friendship and community of action among the scientific workers of different countries. The Society looks forward now to the possibility of collaborating also with any scheme or mechanism for the promotion of international relations in science, which may arise under the general Organisation of the United Nations. We recognize that, through such channels, it may be possible, not only to give most valuable support to the existing unions for int national action in the various fields of scient research, but also to supplement the functions these in many other directions in which the intere of science may yet require to be internationa organized and promoted. The Society stands rea and eager, now as ever, to work with any responsi agency for the restoration and extension of int national friendship and collaboration in science.

In my address to the Royal Society last year, referred to the aim of building anew, and on a fi and broadening foundation, a world community science, as "an aim worthy of our utmost effort a devotion". Can it be doubted now, after what h happened since then, that upon our success achieving that aim may well depend, not only t free progress of science henceforward, but even t survival of civilization ? I have spoken of existi and prospective mechanisms for promoting scienti intercourse between the people of different natior We must use and develop these to the full limit their value, but we shall still want something whi no formal mechanism can restore to us. Meetings national representatives and delegates may, indee do service of great importance to science, as by fran ing and accepting international conventions on uni of scientific measurement, or on technical terminolog but no mechanism which merely brings scienti men together as national representatives, no findi of formulæ or passage of resolutions, will do f science to-day what the world so desperately need

If we are to achieve anything really to meet th need, we must somehow get rid of barriers whic hinder the scientists of different countries from mee ing simply as scientists, for the frank and inform interchange and friendly criticism of each other observations and ideas, in complete freedom fro any national inhibitions or restrictions. Before 191 we were able to claim that science belonged thus t the world, knew no frontiers, was one and indivisibl Many of us had been cherishing the hope that th union of so much of the world in a war for the defenc of freedom—freedom, we understood, for science a for all man's other activities—would have brough with victory, a possibility of reviving this claim an restoring this ideal, which the intervening years ha so shaken and obscured. Even a few weeks ago th trend of events did not appear to encourage tha aspiration ; but we may find, in the end, that it wi suffer less from an open challenge, which all th world can see, than from a more gradual discourag ment.

To all but a few men of science, as to the rest of th world, the use of the atomic bombs on Japanes cities brought the first news of a tremendous scientifi and technical achievement, as well as the recognitio of a new problem of overpowering importance to th world. Scientific workers might well take pride in i as a triumphant verification of a purely scientifi prediction. The main lines of this had been complete before the outbreak of war in 1939, by experimente and theoretical physicists of many countries. W think proudly here of the pioneer part whic our own Rutherford with his pupils and associate had played in the opening of a new science of nuclea physics ; but we recognize that its development wa a widely international achievement. The practica realization in a little over three years of what thes academic scientists had foreseen as a distant poss bility required a scientific and technical undertakin of a new order. It is unlikely that any stimulu her than the urgency of war would have sufficed induce any national, or other, organization embark upon such an enterprise. It is certain at, under the world conditions in which that imulus was applied, the United States of America as the only country in the world where the pro- ct could have been undertaken. The result was prodigy of organization and achievement, both entific and technical; and though, in the nature the case, America made the largest contribu- n even to the team of scientific workers engaged the great volume of theoretical and experi- ental researches still required, we may be glad think that, on that side, the enterprise still wed much to a widely international effort. It drew to its service a large proportion of the nuclear ysicists of Britain and of Canada, with others ho had escaped from the clutches of the German vader in Denmark and in France, and yet others ho had fled before the War from Germany, from ustria and from Italy to conditions of freedom d new opportunity in Britain and the United tates.

The enthusiasm with which the world of science ould normally have received the news of an event such magnitude in scientific history was qualified the unique conditions of its general announce- ent. The world at large has not been slow to grasp e tremendous implications which it may hold for e future of civilization, and the nature of the choice th which it has so dramatically faced mankind. he problems which it has raised are clearly every- dy's concern. Nevertheless, and in spite of certain reats and rumblings, I believe that general opinion ll allow to us men of science, in addition to our mmon rights as citizens, a special claim to be heard the uses which the world is to make of this great w gift of science to mankind. General opinion, I ink, would further recognize that the many scientific orkers who have taken a direct part in this great hievement have a special right and duty to let the orld know how, in the light of their intimate and xpert knowledge, they view the promise and the reat which it offers to humanity. Surely they, if y, have a right to speak; and we others can elcome the firmness and the substantial unanimity ith which many of them have let their opinions be nown. We have a duty, indeed, to the statesmen, ho are carrying this new and heavy burden of sponsibility for the world's future, and who have deal with aspects of the problem in which science not directly concerned. It is a part of that duty, wever, to keep them in touch with the general dy of opinion among the scientific workers of the ee peoples whom they represent, so that, in framing eir policy, they may be confident that the service quired of science to make it effective will be given ith enthusiasm and conviction, and not, if at all, ith a reluctant acquiescence. Most, if not all of you, ll have read words which the Prime Minister spoke the Canadian Parliament, and emphasized by peating them to our own House of Commons a eek ago. "Unless we apply to the solution of these roblems a moral enthusiasm as great as that which ientists bring to their research work, then our vilization, built up over so many centuries, will rely perish." I do not doubt that you will share my ow of gratitude for a tribute which we must try deserve.

It is not fitting that I should discuss here matters hich belong to a much wider constituency than ours, and my particular purpose to-day is to ask you to consider an aspect of this world problem, which is, beyond challenge, our special concern as men of science—the effect of present and prospective developments upon the integrity of science itself. Will any deny our claim to hold that as a sacred trust for the world, and to be alert to defend it from any danger which may seem to threaten it? I believe that we have a duty to be watchful now against a serious danger to it from the intrusion of secrecy, which we know here from long tradition and experience to be alien to the spirit of science as we have known and cherished it. I cannot claim the time which would be required to deal adequately with such a theme. Permit me, however, to bring certain aspects of it briefly to your notice, without attempt at full or ordered discussion.

1. This danger, of course, has not newly arisen with the explosion of the first atomic bomb. We have known it long in connexion with the use of scientific research by industry, and with the relatively minor and accessory part played, until recently, by science in preparing the apparatus of war. Even in those connexions, there was a growing recognition of the detrimental effect of secrecy on the relations between the scientific men concerned and the general scientific community, and a consequent effort to reduce its applications to the minimum which industrial or military opinion would accept.

2. The real and growing danger arises, however, from the new conception of war, due to the breach and consequent abandonment, in rapid succession, of conventions and restrictions which, not long ago, seemed permanent and sacred. Thus by the end of this recent War, step by step, with Germany always leading, the combatant nations had come to regard, as a proper war aim, not merely the winning of mastery over the enemy's fighting forces, but also the compulsion of his surrender by indiscriminate destruction, by any means, of his people and their possessions. This principle of 'total war', as we learned too easily from our enemies to call it, having once been accepted, science found itself no longer a mere accessory of military action, but increasingly a central agent, a direct combatant, and the provider of a limitless vista of destructive possibilities. Last year I spoke of the warning of such developments which the German 'V' weapons had given, and the dropping of the first atomic bombs has now given to that warning a new and a sterner emphasis.

3. Preparation by our enemies for the use of science in such total war, and our own for defence against it by reprisal, have alike involved the binding of a nation's scientific effort to secrecy on a scale beyond all earlier experience. This we accepted readily, with so much else, as a necessity of war. The freedom of science, as of all that made life worth living, was at stake; if by submitting for a while to secrecy we could help to save that freedom and to establish it for ever, we could not hesitate; but we must be watchful now against any easy assumption that that submission will be continued into peace.

4. As has now been recognized by international pronouncement, it cannot be assumed that the atomic bomb, or any contrivance using the release of atomic energy, represents the only direction, or even of necessity the most effective one, in which science could be perverted to the purposes of this 'total war', as a direct agent for the destruction of one people by another, or of dominance by the threat of it. The atomic bomb has given immediate prominence to the

problem, but the world might have had to face it, even if the attempt to release atomic energy had failed, or had never been made. The nations, in fact, have now to decide how they intend to use the powers and the resources which science stands ready to offer in growing abundance. Will they let science work again and henceforward in freedom, once more as an international community, and use what it offers for the raising of all mankind to levels of material prosperity and of culture above any that we can picture ? Or will they try still to bind science to secrecy, for the competitive invention of ever more effective means of destruction, and thus hold civilization in instant peril of dissolution ? It is surely our duty as men of science to help the world with our knowledge to make that decision, and to make clear our own views and intentions.

5. The danger to science from the intrusion of secrecy, against which I suggest that we need to be alert, does not arise, of course, simply from the question whether a particular technical invention shall be given away at once, or not until somebody else has made it. If policies now developing can bring about a frank and effective abandonment of all national secrecy about science, we need not, as men of science, be critical of their beginnings. Our experience so far, however, of the application of secrecy to science for military or industrial advantage must keep us on guard. It has not, in our experience hitherto, dealt with inventions which can, once for all, be locked up or given away. The most that it has hoped to achieve has been to keep its particular employer, at each new stage, a jump ahead of his rivals. What we have now to fear is that, in default of the international agreement which we must hope and work for, national military secrecy should try to maintain, or to extend, its war-time dominance. If that were to happen, we must expect it, with its new experience of the possibilities of science in total war, to be watchful for any advance, whether fundamental or technical, whether in nuclear physics or in any other progressive field of science, which could be impounded and put under seal for war-like preparation, presumably under the name of 'security'. It is impossible to forecast how much of science might thus become involved. The release of atomic energy is yet a novelty, and we have to think what might be made of it, for good or ill, twenty, thirty or forty years ahead. I think that we, as men of science, should make it clear to the world that, if national military secrecy were allowed thus progressively to encroach upon the freedom of science, even if civilization should yet for a while escape the danger of final destruction, a terrible, possibly a mortal wound would have been inflicted on the free spirit of science itself, to the immeasurable loss of what it stands ready to offer to a wiser world.

6. I do not believe that there is any division of opinion on this issue among scientists, anywhere in the world, in so far as they are able to express it simply as scientists. We scientists of the United Nations, in despite of all our normal traditions and instincts, were ready to submit for years to any secrecy or restriction which could help or hasten victory in the War for the world's freedom. The War has been won, and we shall not be ready to accept, as its result for science, a tightening of the chains. We have the right to expect that its freedom will be restored; and the freedoms which we ask for science are freedom from secrecy and freedom from national barriers.

7. Secrecy as the enemy, and resistance to t attempt of authority to impose it, are no n experiences for science or for scientists. Giorda Bruno was burned at the stake and Galileo w imprisoned and threatened, because they refused be secret about discoveries which were thought to harmful to religion in their day; and, in a lat century, there was an attempt, for a like reason, discourage scientific men by moral ostracism fro telling the truth as they had seen and discovered Science was not halted, the world still moved, the mor stature of mankind was raised by the encounter, a organized religion gained more from it in wisdom th it lost in intellectual dominance. We do not kno yet who, or how many, of Europe's men of scienc in the terrible years now closing, have suffered for t scientific truths which political tyrannies desired suppress or to distort. Unless the growth of inte national understanding and confidence can no prevent it, unless efforts to outlaw the abuse science for 'total war' should succeed, science ma find itself again facing an attempt to impose secre upon it, this time in the interests of national suspici and rivalry, and in flat negation of its true service mankind. If that danger should threaten, can v hope that the scientists of all the world may y stand together against it, determined to preser the integrity of science, to prevent its further pe version from its proper and beneficent uses, and save civilization from misusing science for its ow destruction ?

Our Charter of 1663 lays down, as the object of t Royal Society, "promoting by the authority experiments the sciences of natural things and useful arts, to the glory of God the Creator, and t advantage of the human race". Each of us may re these old words to-day in terms of his personal co victions. Freely to seek "by the authority of exper ments" and freely to proclaim the truth as scien reveals it, for its own beauty and excellence and f the help, the healing and the enlargement of th means of happiness which it can bring to all mankin —does any man of science, anywhere in the worl whatever his creed or his loyalties, desire for scien any aim but this ? The old mandate still embodi the purpose for which the Royal Society has stood f more than 280 years, and still must stand, as a beaco to the world and as one of its centres of inspiratio

AN ELECTRICAL HYPOTHESIS OF SYNAPTIC AND NEUROMUSCULA TRANSMISSION

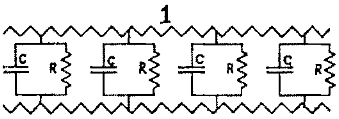
By PROF. J. C. ECCLES, F.R.S.

Physiology Department, University of Otago

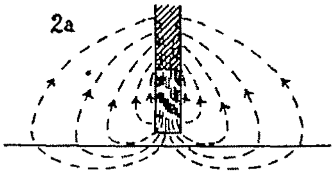
SINCE 1933 the transmission of impulses acro synaptic or neuromuscular junctions (hencefort called junctional transmission) has been the occasio of a controversy[1]. The electrical hypothesis ha had the grave defect that (except for the falsifie isochronism theory) it has never been stated i such precise terms that it could be subjected t crucial tests[1,2,3,4,5,6]. On the other hand, th chemical hypothesis in its original form (acetylch line as transmitter) was falsified by an investigatio of the action of eserine, and has had to be modifie by the addition of *ad hoc* hypotheses[7]; but t ation remains unsatisfactory because there seems e hope of testing these *ad hoc* hypotheses inde- dently, and because recent work suggests that mical transmission plays a subordinate or negli- e part in junctional transmission in sympathetic glia[3] and the spinal cord[4]. Meanwhile, during last eight years important advances have been de in the investigation of the electrical properties erve fibres, and of the electrical events occurring junctional transmission; hence the time has med opportune to elaborate on these bases an trical hypothesis (or model) of transmission that apable of experimental test.

he initial assumptions of the hypothesis are: That the geometrical situation at the junction y be schematically represented by the terminal ve fibre ending as a cylinder with a closed end in se apposition to the large plane surface of the effector (nerve or muscle), as is shown in longitudinal tion in Fig. 2. (*B*) That in general the surface mbranes have the electrical properties demon- ted for peripheral nerve and muscle membranes— embling a leaky condenser (in Fig. 1, *C* is about μF and *R* about 400–1,000 Ω per sq. cm.) ich has a resting charge of 50 mV., and which o acts as a rectifier[8,9,10,11], outwardly directed rents (cathodal) decreasing *R* to as little 1/13, while anodal currents have the reverse ect. For present purposes the inductance[8] of the mbrane will be ignored, because the absence of illatory potentials in the electrical responses of mal vertebrate nerve and muscle suggests that it much smaller than in the squid. Both exterior d interior have the conductivity of a weak (0·6–) per cent) salt solution. (*C*) That the junctional ion of the effector cell has unique electrical perties, in that cathodal polarization (lowering of ting charge) sets up a graduated 'local re- nse'[12–18] with a temporarily irreversible and ge diminution of potential and resistance (cf. ref. 8, 46), but not the all-or-nothing membrane 'break- wn' characteristic of the propagated impulse. It y be likened to the nerve membrane in a refractory, esthetized or deteriorated condition[15,18,19].

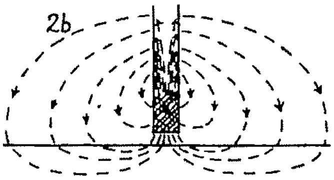
Assumption *A* is based largely on the generally epted histological picture of the junction, but ctrical investigation also shows that there is a nsverse membrane[1]. Assumption *B* is based on ect measurements on nerve and muscle, and on evidence that nerve cells resemble nerve fibres in ir electrical excitability[8] and in the propagation impulses from a nerve cell to its axon and vice sa[8,20]. Assumption *C* is based on the responses nerve under special conditions (as above) and on ect observation of the electrical response set up a nerve impulse at an isolated neuromuscular ction before and during curarization[21]. This l-plate potential rises smoothly to the full height the spike potential without showing the sudden lexion characteristic of impulse initiation. The pulse appears to be initiated a little later by an acent region of the membrane when it reaches a tical intensity of catelectrotonus. Progressive arization produces *pari passu* a diminution in the d-plate potential, impulse initiation occurring acently at lower end-plate potentials and after ger delays. It may therefore be assumed that junctional region of the muscle is specialized to e 'local responses' of high and graduated intensities hout incurring the membrane breakdown charac- stic of the impulse[21]. This evidence of its unique electrical properties can be related to its well-known unique pharmacological properties[22,23]. Assumption *C* is extended to the synaptic regions of nerve cells.



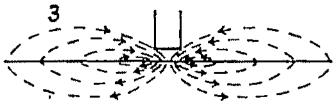
1



2a



2b



3

It appears that, assuming *A* and *B*, we have to expect that the current generated by an impulse propagating into a nerve terminal will in part penetrate the effector cell and give a diphasic action, first an anodal focus at the junctional region with a cathodal surround (Fig. 2*a*), which quickly reverses when the peak of the impulse reaches the junction (Fig. 2*b*). The penetrating current will be limited by polarization of the membrane condensers, and in the initial phase by the increasing resistance at the localized anode. On account of its much larger area, the membrane resistance at the cathodal surround will be so much lower that its simultaneous diminution will be relatively insignificant in tending to increase the flow of penetrating current. However, in the second phase the situation is reversed, because the lowering of the initially high resistance at the localized cathode will have a preponderating effect in increasing the flow of current; hence a much larger penetrating current will flow in the second phase than in the first phase, the current being as it were canalized through the localized low resistance at the cathode (cf. ref. 8, Fig. 3). According to assumption *C*, this cathodal current of high density would evoke at the junctional region of the effector cell an intense 'local response' which would run through a cycle of increasing and decreasing intensity, much as does the spike response of a propagating impulse[15,16,17,18,19]. This local response thus would outlast the second phase of penetrating current flow, and provide a relatively enduring focus of very low polarization and resistance through which adjacent regions of the membrane proceed to discharge (Fig. 3). (Assumption *C* here is essential for the hypothesis.) The anodal surround of Fig. 2*b* therefore gives place to a catelectrotonically polarized surround which spreads spatially according to the 'core conductor' theory. Such catelectrotonic potentials have been observed to play an essential part in all junctional transmissions so far investigated. It has further been shown that these potentials have a time course which may be interpreted as due to a brief active depolarization and a passive exponential decay governed by the electric time constant (the product CR in Fig. 1) of the membrane[4,6,15,24,25]. In the present theory the active depolarizing action is provided by the local response of the junctional region of the effector cell, not directly by currents generated in the nerve terminals, as has hitherto been assumed in hypotheses of electrical transmission.

The remainder of the hypothesis is on conventional lines, the catelectrotonus setting up an impulse in the effector cell when it attains a threshold value, just as occurs with an artificially evoked catelectrotonus[4,6,15,25]. With muscle the impulse arises in the membrane adjacent to the end-plate region[21]. With nerve cells the catelectrotonus from the diverse synaptic region sums to give the synaptic potential, which provides a satisfactory explanation of all the phenomena hitherto attributed to the central excitatory state[3,4,24].

Thus the sequence of events in junctional transmission is envisaged as: (1) Impulse in terminal nerve fibre generates a current which gives a diphasic effect at the junctional region of the effector cell with a total duration of probably not more than 1 m.sec. in mammalian muscle and spinal cord: (*a*) initial anodal focus with cathodal surround; (*b*) more intense cathodal focus with anodal surround. (2) This cathodal focus sets up a brief and intense local response at the junctional region. (3) From this local response a catelectrotonus spreads decrementally over the effector cell membrane. (4) A propagated impulse is set up in the effector cell if this catelectrotonus is above a critical value; if it is below, then as the local response subsides, the catelectrotonic surround decays passively.

The hypothesis offers an explanation of the following observations on junctional transmission.

(*a*) Irreversibility of junctional transmission would be predicted because an impulse in the effector cell would sweep past the nerve terminals on the surface and exert on them also the third phase of anodal depression as predicted by the theory of electrical interaction and observed in artificial synapses[2,26,27], so abruptly terminating the local cathodal effect.

(*b*) The delay in onset of the local response and catelectrotonus of the effector cell (synaptic or junctional delay) is attributable to the initial penetrating current setting up an anodal focus, which has to be removed by the reversed current before the cathodal focus would be built up sufficiently to generate the local response; that is, there would be a delay until the impulse at the nerve terminal was on its declining phase. The observed value of about 0·6 m.sec. for mammalian neuromuscular junctions[25] and central synapses[4] accords well with this explanation. A further delay of about 0·2 m.sec. is attributable to the time of rise of the catelectrotonus to the threshold for impulse discharge[4,25].

(*c*) The brief phase of low resistance (additional to the catelectrotonic effect) during the initial part of the end-plate potential[11] is attributable to the local response at the junctional region, which, because of its sharp localization, would contribute relatively more to current flow than to potential.

(*d*) Analysis of junctional potentials gives a time course for the active depolarizing agent corresponding to that expected for the local response of the effector cell[4,6,15,24,25].

(*e*) If the junctional region cannot give the all-or-nothing impulse response (assumption C), its 'local response' might be expected to survive
transmission of a muscle impulse whether gener
adjacently or propagating past—as is found to o
for the active depolarizing agent[15].

(*f*) The hypothesis would predict that a
propagated catelectrotonus of the effector cell,
example, a synaptic potential, would give rise
sharply localized cathode at the nerve terminal
hence produce there the same conditions as occu
in the effector cell in Fig. 3. Catelectrotonus sprea
from this focus provides an explanation of the d
root potentials[28].

In its present largely qualitative form, the tes
of the hypothesis may be considered at two le

(i) The picture of the diphasic flow of penetra
current and the cathodal focus is based on assu
tions A and B. In connexion with the pre
hypothesis, assumptions A and B are to be conside
in the main, as established rather than as ope
tests by experiments on junctional transmiss
The mechanism of this action has already been in
tigated in the artificial synapse or ephapse made
two nerve fibres in close apposition[2,14,26,27]. (F
2, 3, 4, and 5 of the first paper are particul
pertinent as they show a 'terminal' effect with
initial diphasic wave generating a local resp
exactly as predicted by the present hypothesis.
oscillatory decline of this local response may
related to the high inductance of the squid n
membrane[8].) Further study of ephaptic transmis
will provide a test for this aspect of the hypothe

(ii) The hypothesis states that the cathodal f
at the junctional region is adequate both in inten
and time course to set up the observed local respo
the subsequent spreading catelectrotonus and fin
the propagated impulse. These predictions sho
be testable by transmission experiments. In pa
cular the tests would attempt to evaluate the
of the chemical transmitter, which is relegated
a subsidiary position by the present hypothe
The action of eserine indicates that the juncti
of nerve-muscle[7], the sympathetic ganglion[3], and
spinal cord[4] form a series of decreasing significa
for chemical transmission.

A crucial test for the electrical hypothesis
be its ability to explain the junctional block
curare. Since curare is known to act specifically
the junctional (end-plate) region of muscle[22],
since the block is explained by the observed depres
of the junctional potential[8,21,25], the simplest expla
tion is that curare depresses the local response
up at the end-plate by the cathodal focus, t
is, it depresses the electrical excitability of
end-plate. In a recent attempt to test this
electrical stimulation of the isolated neuromusc
junction before and after curarization[23], the initiat
of propagated muscle impulses was used as
criterion of end-plate excitability. Yet, if the e
plate region reacts by local responses rather t
by propagating impulses (assumption C), it see
probable that this investigation tested the exc
bility of regions adjacent to the end-plate, confirm
the previously observed absence of curare act
there; that is, it provides no evidence for or aga
a specific depression of end-plate excitability. H
ever, if curare blocks solely by its known depress
effect on chemical transmission, then, in a very d
curarization, the residual catelectrotonic effe
produced by the cathodal focus (that is, by electri
transmission) should be observable uncomplicated
chemical transmission. The problem of curare act

articularly significant, because it also specifically ks transmission through sympathetic ganglia[24], re chemical transmission seems to play a subor- ate role[3].

n conclusion, it may be stated that the present othesis will have to stand up to many severe s, particularly pharmacologically. Mathematical elopment has been beyond my competence and y be premature, though it should be possible; the absence of quantitative prediction as regards nsity of action is a grave defect. Nevertheless, the basis of the properties observed for peripheral ve and muscle membranes, the hypothesis gives tatement of electrical transmission sufficiently cise (particularly as regards time course) for erimental testing, offers a coherent explanation many previously unrelatable observations, only e of which are mentioned in this preliminary ount, and has already proved fruitful in suggesting experimental investigations.

wish to thank Dr. K. R. Popper for his stimulating helpful criticism.

OBITUARIES

Dr. J. C. Merriam

he death on October 30 of Dr. J. C. Merriam the age of seventy-six will be deplored by all ontologists and many other scientific men.

After a training under von Zittel in Munich, rriam went to the University of California to teach eontology and historical geology, and in time ame professor and head of the Department of ology.

ot long after his appointment, Dr. Perrin Smith, o was working on ammonites, gave Merriam some gmentary remains of reptiles from the Upper assic Trachyceras beds of Shasta Co., North ifornia. These proved to belong to Ichthyosauria, Merriam based on them the first satisfactory ount of any Triassic member of that group. The obvious importance of this find enabled Merriam to interest Miss Alexander, and with her help he was able to take expeditions into the field, which, in several years, not only collected much Upper Triassic material but also found new localities in Nevada where well-preserved Middle Triassic Ichthyosaurs could be collected. The whole material was described in an admirable monograph.

Merriam also recognized that some of his material was not ichthyosaurian but belonged to members of an entirely new order of aquatic reptiles, which he described as the Thalattosauria in another splendid monograph.

Dr. Merriam then turned his attention to fossil mammals, exploring the John Day region of Oregon, giving us an account of the stratigraphy, and descriptions of many new or little-known animals found in it. From this, led by an accidental find, he went on, with the aid of his students, to explore other regions of the western part of the United States, work of great importance because our knowledge of Tertiary mammals depends so largely on materials from the Plains and Great Basin of the Rocky Mountains, the whole country to the west having been barren.

Merriam's well-directed and long-continued explorations not only showed us many successive faunas from the west, but also in some cases gave us mammal faunas from rocks in a marine succession, and thus for the first time enabled us to correlate the terrestrial formation of the interior of the continent with the 'normal marine succession'.

In 1920, Merriam was appointed president and chief administrative officer of the Carnegie Institution of Washington, but he still retained his interests in palæontology, himself continuing to work on fossils and supporting the work of other men. After his appointment to Washington, Merriam became much interested in the problem of the time at which man first appeared on the American continent, drawing up a detailed discussion of the evidence in a report to the Sixteenth International Geological Congress in 1934. In this he showed that man had been a contemporary with some extinct mammals in America.

But Merriam's interests ranged widely: he wrote much on national parks, on the wide diffusion of culture among the 'common men', on many social problems of the modern world, and on spiritual values. He was in fact a man entirely worthy of the influential position he filled, and he was also a palæontologist of the first rank.

D. M. S. WATSON.

Prof. Velyien Henderson

WE regret to record the death of Prof. Velyien Ewart Henderson, of Toronto, on August 6 at the age of sixty-eight. Prof. Henderson was born and educated in Canada and took his M.B. at Toronto in 1902. After a period as demonstrator in the University of Pennsylvania he studied at Prague and at Marburg under Hans Horst Meyer. He was appointed demonstrator of physiology in Toronto in 1904, lecturer in pharmacology in 1906 and professor of pharmacology in 1909. Except for a period of service in the Canadian Expeditionary Force during 1916–18, he was at Toronto for the remainder of his life.

At Marburg, Henderson worked on diuresis and on the salivary glands. With Otto Loewi he discovered that the vasodilator nerves in the chorda tympani are not antagonized by doses of atropine, which antagonize the corresponding effect of drugs acting like acetylcholine. This fact provides a complication in the theory of the mode of action of cholinergic nerves, and this topic provided Henderson with one of the interests of his life. In 1932, with Roepke, he demonstrated the liberation of acetylcholine in salivary glands on stimulation of the nerve chorda tympani, and much other work on this and allied drugs has come from his laboratory.

Henderson's main interest in recent years was in anæsthetics. With G. H. W. Lucas he was responsible for the discovery of the properties of cyclopropane as a general anæsthetic in 1929. Though it is difficult to make and administer, this gas has been widely
used because it is a powerful anæsthetic without t
actions and is rapidly eliminated. This discov
formed part of a prolonged pharmacological stud
the properties of a number of similar substances.
addition to these major investigations, Hender
published papers on a wide range of other top
including morphine miosis, expectorants, intest
peristalsis, the respiratory centre, and the mechan
of erection. The late Sir Frederick Banting o
much to the encouragement given to him by H
derson in the early days of work on insulin.

Pharmacologists all over the world mourn
passing of a very lovable man who achieved m
for the advancement of knowledge and the wel
of mankind.

J. H. GADDUM

NEWS and VIEWS

Anniversary Meeting of the Royal Society

SIR HENRY DALE completed his term of office as president of the Royal Society at the anniversary meeting on November 30, and the main part of his address is printed elsewhere in this issue (p. 677). Speaking of domestic affairs, Sir Henry recorded the Society's thanks to the several people who undertook the guardianship of its historical treasures, now safely returned to London. He also announced that the Society is to increase the number of annual elections to twenty-five. Sir Henry himself, when he was a secretary of the Society, had a part in the movement which led in 1931 to the increase of maximum annual admissions to seventeen from fifteen, at which figure it had remained from the time when limitation was imposed eighty-three years before. In 1937, the number was raised to twenty; and now it is to be made twenty-five. This action has been taken in recognition of the recent rapid growth in number of those who have produced evidence of real scientific achievement. Sir Henry also referred to the election this year of two women to the fellowship of the Royal Society, following an alteration to the statutes to elucidate a legal position which had existed since 1919. He admitted that the decision was contested, but expressed his belief that the change was a normal adjustment of the Society's practice "to the growth in extent and distinction of women's contribution to the advancement of science by research".

The officers of the Royal Society as now announced are: *President:* Sir Robert Robinson; *Treasurer:* Sir Thomas Merton; *Secretaries:* Sir Alfred Egerton and Dr. E. J. Salisbury; *Foreign Secretary:* Prof. A. V. Hill; *Other members of Council:* Dr. C. H. Andrewes, Dr. W. T. Astbury, Prof. P. M. S. Blackett, Dr. E. C. Bullard, Prof. I. de B. Daly, Prof. R. A. Fisher, Dr. C. Forster-Cooper, Prof. F. E. Fritsch, Dr. S. Goldstein, Prof. E. L. Hirst, Prof. W. V. D. Hodge, Dr. G. M. Holmes, Prof. H. W. Melville, Prof. R. A. Peters, Dr. D. R. Pye, Prof. S. Zuckerman.

Sir Robert Robinson: President of the Royal Society

SIR ROBERT ROBINSON, Waynflete professor of chemistry in the University of Oxford, who has just been elected president of the Royal Society, is recognized throughout the scientific world as one of the most outstanding and versatile of organic chemists.
His researches not only embrace all fields of p
organic chemistry but also include notable contri
tions to subjects of biological interest, such as a
malarials and phthioic acid. As a research stud
under the late Prof. W. H. Perkin, Robinson
early initiated into the chemistry of the alkal
and other natural products, and he soon became
outstanding figure in the famous Manchester sch
The unique collaboration between Perkin and Rol
son thus established was continued until the form
death in 1929. While still less than thirty year
age, as professor in Liverpool, Robinson publis
his famous synthesis of tropinone, noteworthy
account of its simplicity and intuitive brilliance. T
was quickly followed by a theory of biogenesis
plant products which collated for the first time
apparently dissimilar alkaloidal structures and wh
still stands as one of the most outstanding contri
tions to the chemistry of natural compounds. Am
other significant investigations in this field, ment
may be made of Robinson's morphine formula,
universally accepted, and also his classical work
the elucidation of the structures of brucine
strychnine.

On his return to Manchester as head of the Dep
ment of Organic Chemistry and with more stude
available, Robinson's research programme rapi
expanded, and he turned his attention to the prob
of the anthocyans, the naturally occurring pigme
of flowers and fruits. The synthesis of these
achieved in a comparatively short time and c
stitutes possibly the most brilliant example of plan
research in organic chemistry. Less widely rec
nized but of equal importance is his work on
synthesis of the anthoxanthins, whereby read
accessible routes were secured for the preparation
a wide range of many naturally occurring flavo
flavanols and *iso*flavones. In 1930, Robinson w
to Oxford as Waynflete professor. By 1935 m
attention was being focused on sterols and rela
compounds, and Robinson, together with his stude
and collaborators, embarked upon the diffic
problem of the synthesis of the secondary sex hor
ones. Once again his mastery of synthetic meth
has been demonstrated in a series of memoirs n
worthy for their freshness of approach. Arising
of this work, Robinson, in association with P
E. C. Dodds, was responsible for the discovery
stilbœstrol, the first synthetic œstrogen.

During the war years, notwithstanding much he
and responsible work on behalf of the Governm

Sir Robert Robinson still found time for new researches, and it is no secret that for the past five years he has concentrated much attention upon the problem of the structure and synthesis of penicillin. Reference must also be made to his electronic theory of organic reactions which, classifying on a common basis a diverse mass of data, has had a profound influence on the development of chemical thought. Sir Robert Robinson has indeed imprinted his genius upon every branch of organic chemistry. Throughout his career, students have flocked to his laboratory from all parts of the world, and while still less than sixty years of age he has the satisfaction of seeing his former students occupying some of the most prominent positions both in academic life and in industry.

Rowett Research Institute: Dr. D. P. Cuthbertson

David Paton Cuthbertson, who has been appointed head of the Rowett Research Institute in succession to Sir John Orr, graduated B.Sc. from the University of Glasgow in 1921 as a pure chemist. He was awarded a Ministry of Agriculture scholarship and commenced his research work in the biochemical laboratory of the Institute of Physiology at Glasgow. He soon realized that to carry out effective investigations in biochemistry he must have more biological knowledge, and accordingly he resigned his scholarship and began the study of medicine. He graduated M.B., Ch.B. in 1926 and, shortly after graduation, he was appointed the first clinical biochemist at the Royal Infirmary, Glasgow. He rapidly developed this post and managed to have attached to his laboratory a small number of beds for the study of metabolic disorders. In 1934 he returned to the University of Glasgow as Grieve lecturer in physiological chemistry. The Medical Research Council in 1943 applied for the loan of his services to act on its secretariat. In this last post he was appointed scientific secretary to a number of the Council's sub-committees and thus gained a very wide experience of the varied research work carried out on behalf of the Council. Earlier this year he accepted an invitation from the Government to visit Newfoundland to report and advise on the means requisite to alleviate the recognized nutritional deficiencies. He obtained the degrees of D.Sc. in 1931 and M.D. with honours in 1937. He also worked for a period in the biochemical laboratory of the University of Leipzig under Prof. Karl Thomas. Dr. Cuthbertson's research work has been mainly in the metabolic field, and particularly that of protein metabolism. His most interesting and outstanding contribution has been a series of papers on the metabolic reactions of tissues to injury with special reference to the effects of fracture of bones and of the immobilization of limbs.

Physical Society Awards: Duddell Medal

The Duddell Medal of the Physical Society is awarded at suitable intervals, usually annually, for the invention of scientific instruments or of materials used in their construction. The Council of the Society made the twenty-ninth (1945) award to Prof. J. T. Randall, professor of natural philosophy in the University of St. Andrews, for his very valuable work on phosphors and the cavity magnetron. The presentation is to be made on December 12, when Prof. Randall will deliver an address at a meeting of the Society at the Science Museum.

Before the War, Prof. Randall had made important contributions to the X-ray study of structure (notably those of carbon, graphite and glasses) and was also an early worker in electron diffraction. His investigation of luminescence just before and during the early part of the War, and his elucidation of the nature and depth of the 'electron traps' in phosphors, was a fine piece of work on the experimental side, and showed a complete grasp of theory. During 1939–43 he worked for the Admiralty as a member of the special team at Birmingham under Prof. M. L. E. Oliphant, mainly concerned with the research and development of valves for operation on high powers for centimetric radar. Assisted by Boot, Randall was responsible for the very brilliant adaptation of the already-known split-anode magnetron into the cavity magnetron, which enabled exceedingly high powers to be provided on centimetric waves. Randall's cavity magnetron and Sutton's *V-M* valve are basic to the present high pitch of perfection attained in British radar technique and in that of the United States; without them radar might have been relatively ineffective. Both units are destined to play important peace-time parts, particularly in air and sea navigation.

Charles Vernon Boys Prize

By the will of Sir Charles Boys, provision was made for the foundation by the Physical Society of a memorial to one of its most distinguished past presidents, and the Council of the Society decided that it should be a prize to be awarded annually for experimental work either still in progress or completed not earlier than ten years before the date of the award. The first (1945) prize has been awarded to Dr. A. H. S. Holbourn, of the Clarendon Laboratory, Oxford, for his successful measurement of the angular momentum of circularly polarized light. Before this work, it was uncertain whether this momentum really was $h/2\pi$. Holbourn succeeded in suspending a half-wave plate on a $\frac{1}{4}\mu$ silica fibre and, working under good vacuum conditions, he was able to measure the torque produced when the direction of rotation of circularly polarized light was reversed in its passage through the plate; torques as small as 2×10^{-11} dyne cm. were measured with an accuracy of 3 per cent. Apart from its great theoretical significance, this experiment represents a most delicate piece of manipulative work comparable with Boys' construction of the radiomicrometer. It was described briefly in *Nature* (**137**, 31; 1936) and the *Journal of Scientific Instruments* (**16**, 331; 1939) and at greater length in a D.Phil. thesis (Oxford, 1938). Historically, it is interesting to note that the work was carried out in a compartment of the same cellar of the Old Clarendon Laboratory in which Boys himself measured the mean density of the earth. The presentation will be made at the meeting on December 12.

Organic Chemistry at the Royal Technical College, Glasgow: Appointment of Dr. F. S. Spring

The chair of organic chemistry at the Royal Technical College, Glasgow, last occupied by the late Forsyth James Wilson, has now been filled by the appointment of Dr. F. S. Spring, of the University of Manchester. Dr. Spring graduated with honours in chemistry at the University of Liverpool in 1928, and while holding a United Alkali research scholarship followed by a University fellowship he carried out research on the chemistry of the sterols with Prof. I. M. Heilbron, being duly awarded the Ph.D.

degree. His first academic appointment was as assistant lecturer in organic chemistry at Manchester in 1930, under the late Prof. Lapworth. With the appointment of I. M. Heilbron to Manchester on the retirement of Lapworth, the Heilbron and Spring collaboration was resumed, and many papers, particularly on the chemistry of ergosterol, vitamin D and related compounds, testified to the success of the collaboration. With the departure of Heilbron to the Imperial College, London, Spring continued his interest in the chemistry of natural products, going on to studies in the triterpene group and especially the constitution of the α- and β-amyrins. He was awarded the D.Sc. (Manchester) in 1937, and made a senior lecturer in 1941. More recently, with an active research team, he has broken new ground in studies on the application of the Hofmann reaction to the synthesis of heterocyclic compounds, and in addition has carried out investigations for the Colonial Products Research Council.

At Manchester, Dr. Spring proved himself a very successful teacher and an able lecturer, his interest in the chemistry of natural products adding enthusiasm to his lectures to medical students and others. He has always been a staunch supporter of the Chemical Society, being at present a member of its Council, and, as well as being a frequent contributor of original papers, he has taken a very active part in the compilation of the annual reports published by the Society. During the War, Dr. Spring has acted as senior gas adviser to the North-West Regional Commissioner, and was responsible for the training of gas identification officers in this area, and, in association with Prof. A. R. Todd, carried out research for the Ministry of Supply.

Statistics in the Modern State

In his presidential address to the Royal Statistical Society on November 22, Lord Woolton said that the progress in statistics in public affairs in Great Britain during the last half-century has enabled the reading public to form political opinions and provided precise information for Ministers of the Crown, business men and the trade union movement. By 1939 the supply of information was comprehensive enough to show the size of the resources of the country and how they were being used; but there were many gaps in the information available, and those who found themselves in 1939 responsible for the government of the country in the rapidly changing conditions of the War had very little to help them. The proved competence of the statistician, both in the field of financial forecast and in the operations of Government, have given much stimulus to those who believe in national planning, and in particular, to its use in preventing economic waste and personal tragedy. Unemployment is the most urgent social problem confronting the modern State, and Lord Woolton believes that the use of the statistical method of ordering those operations of our economic life that are within the control and competence of Government can in a large measure solve the problem. We must have knowledge of facts, and capacity to forecast future trends from those facts; but it is useless and aggravating to call for information in greater detail than is necessary to provide proper guidance to action. Enumerating the principal classes of statistics that must be obtained for the efficient operation of an employment policy, Lord Woolton said that to collect the information involves maintaining close collaboration between statisticians in Government services and their professional colleagues in trade associations, in the universities and research institutes.

Committee on Scientific Man-power and Resources

Mr. H. Morrison, Lord President of the Council announced in the House of Commons on November 29 that he has appointed a Committee "to consider the policies which should govern the use and development of our scientific man-power and resources in the next ten years". The Committee is being asked to produce an early interim report to facilitate forward planning in fields which are dependent on the use of scientific man-power. Later the Committee will be asked to make recommendations for the establishment of permanent machinery for carrying out surveys into the best use of the scientific resources of Britain in the national interest. The Committee is constituted as follows: Sir Alan Barlow (temporary chairman), Sir Edward Appleton, Prof. P. M. S. Blackett, Mr. Geoffrey Crowther, Sir Alfred Egerton and Sir George Nelson.

Engineers' Study Group on Economics

Sir Richard Paget, retiring president of the Engineers' Study Group on Economics, at the annual general meeting held on December 1, announced that Sir John Boyd Orr will be president for the coming year, with Sir Geoffrey Bracken (formerly finance minister to the Madras Presidency) as deputy president. Sir Richard outlined some tasks that the Group might undertake. There is still an urgent need for the clarifying of public opinion throughout the world on the true role of money and as to the principles by which all nations should be guided in providing their national currencies and exchanging their surplus products for the common good of the world at large. Gold—a valuable metal—which could be profitably employed in making glorious and everlasting works of art for the admiration and delight of posterity, still lies buried in vaults. The problem of 'the role of money' might be made the subject of an impartial investigation by a team of economists and financial experts from many countries, similar to the teams of workers who, during the War, successfully attacked many scientific problems.

Sir Richard Paget further stated that the Ethics Section of the Engineers' Study Group, together with the Religious and Scientific Research Group, are paying special attention to developing an international ethical system, a code to which men and women of all nationalities, and all creeds, could agree. A stable world will need stable ethical foundations, fearlessly built on the rock of ascertainable truth—on fact rather than on faith.

Shirley Fellowship Awards

The British Cotton Industry Research Association has awarded the first two Shirley Fellowships for postgraduate research to Mr. F. Brown and Mr. T. G. Halsall, both of the University of Manchester, who will work on carbohydrate chemistry under the direction of Prof. E. L. Hirst. Mr. Brown has been working on chromatographic and other methods for the separation of closely related carbohydrate derivatives, and Mr. Halsall has been studying the action of periodate ions on polysaccharides. The new methods of end-group determination thus developed will be applied to problems in the chemistry of starch and cellulose. The fellowships date from January 1, 1946.

Acoustic Control in the Flight of Bats

At the discussion following Prof. H. Hartridge's paper on "Acoustic Control in the Flight of Bats" ecently read before the Linnean Society (*Nature*, 56, 490; 1945), Mr. A. J. Wilmott reported that when he was a child there was in Cambridge a well-known blind organist who was accustomed to walk about the town without the usual aids. When asked how he did it, he replied that the echoes, for example, rom a brick wall, or from a low wall with railings above, appeared to him to be very different. By recognizing the different types of echo he could tell what was near him, and thus locate where he was. This acute sense of hearing even extended to the recognition—at just over two paces—of four ladies who in curiosity to see what would happen stood quite still right across the pavement in the organist's way. The organist hesitated a pace and then came to a complete stop. One of the ladies laughed; thereupon she was instantly recognized by the organist, who said, "I thought there was somebody there". This appears to show that sounds of ordinary frequencies have actually been used by man in much the same way as supersonic sounds are used by bats. (See also p. 692 of this issue.)

Royal Asiatic Society of Bengal

In celebration of the bicentenary of the birth of Sir William Jones, its founder and first president, in January 1946, the Royal Asiatic Society of Bengal is arranging a Conference on Indology and Oriental Culture in the first week of January, and terminating with a banquet on the Foundation Day, January 15. Representatives of learned societies in India, China, U.S.S.R., Iran, Turkey, Great Britain and the United States, as well as individual leaders and patrons of learning, have been invited to participate in the celebrations. A booklet issued by the Society outlines the programme of special publications which has been undertaken in connexion with the bicentenary and includes the address given to the Society by Dr. L. L. Fermor on its one hundred and fiftieth anniversary in January 1934, together with Sir John Anderson's speech on the same occasion, and a list of exhibits at the conversazione. The special publications now projected include a new series of monographs to which Dr. S. K. Mitra is contributing one on the upper atmosphere; a complete author- and subject-index of all the important articles in the Asiatic *Researches* and the *Journal* and *Proceedings* of the Society up to the end of 1945; and a commemoration volume to which Dr. S. L. Hora, Dr. K. P. Brocias and Dr. K. N. Bagchi have been invited to contribute an article on the progress of scientific studies in India.

Atomic Energy and its Implications

A joint meeting of the American Philosophical Society and the U.S. National Academy of Sciences to discuss "Atomic Energy and its Implications" was held in Philadelphia during November 16–17. The following papers were read: Prof. H. De Wolf Smyth, "The Scientific Background of the Atomic Bomb"; Prof. J. R. Oppenheimer, "Atomic Weapons"; Prof. R. S. Stone, "The Health Protection Activities on the Plutonium Project"; Dr. J. H. Willits, "The Process of Social Adjustment to Atomic Energy"; Prof. J. Viner, "Implications of Atomic Bomb for International Relations"; Dr. Irving Langmuir, "World Control of Atomic Energy"; Prof. J. T. Shotwell, "The Control of Atomic Energy under the Charter". The Franklin Medal Lecture, on "Atomic Energy as a Human Asset", was delivered by Dr. Arthur H. Compton.

Announcements

Dr. E. S. Russell has retired from the post of director of fishery investigations in the Ministry of Agriculture and Fisheries, but will continue to serve for some time in an advisory capacity.

Mr. R. R. Enfield has been appointed to a new post of chief economic adviser to the Ministry of Agriculture and Fisheries from December 4. Mr. D. A. E. Harkness, senior assistant secretary in the Ministry of Agriculture, Northern Ireland, has been appointed from the same date to succeed Mr. Enfield as principal assistant secretary in charge of the Economics and Statistics Division of the Ministry.

Prof. W. Weisbach, writing from Langeraar (Z.H.) A.95, Holland, states that he has now returned from German concentration camps, and is the sole owner of the publishing house of his partner and father-in-law, Dr. W. Junk, who died in 1942. *Tabulæ Biologicæ*, *Enzymologia*, *Mycopathologia*, etc., will be published as usual again in due course by the firm.

Dr. John R. Campbell, scientific officer on the staff of the Fuel Research Division of the Department of Scientific and Industrial Research, has been appointed lecturer in fuels at the Royal Technical College, Glasgow, in succession to Dr. G. S. Cruickshanks, who has retired.

The Royal Society of South Africa has elected the following as fellows: Dr. A. J. Boyazoglu, for outstanding work on agricultural problems including rural economic surveys in various lands; and Commander B. L. Goodlet, for many-sided researches in electrical engineering both in peace-time and in association with the Royal Navy.

The following appointments, promotions and transfers in the Colonial Service have recently been made: J. D. Hunter-Smith, to be agricultural officer, Tanganyika; G. E. M. Latimer, to be veterinary officer, Nigeria; J. P. Bernacca, to be entomologist, Uganda; E. G. N. Greaves, to be deputy Government chemist, Trinidad; Dr. E. Phillis, to be chief scientific officer, Department of Agriculture, Trinidad; D. Thornton (agricultural officer, Tanganyika), to be senior agricultural officer (soil erosion), Tanganyika; F. W. Toovey (botanist, Nigeria), to be senior botanist, Nigeria; J. A. N. Burra (assistant conservator of forests, Gold Coast), to be assistant conservator of forests, Palestine; W. J. Eggeling (senior assistant conservator of forests, Uganda), to be conservator of forests, Uganda; W. A. Fairburn (senior assistant conservator of forests, Nigeria), to be conservator of forests, Nigeria; C. B. Bissett (senior geologist, Uganda), to be deputy director of the Geological Survey, Uganda; T. Hirst (senior geologist, Gold Coast), to be deputy director of the Geological Survey, Gold Coast.

Erratum.—The British publishers of the book "Patrick Geddes" reviewed in *Nature* of November 24, p. 612, are the Oxford University Press, Amen House, Warwick Square, London, E.C.4, and not Messrs. Chapman and Hall, Ltd., as stated.

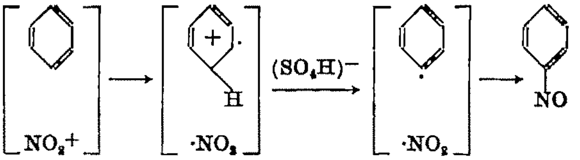
Univalent Electron Transfers in Aromatic Nitration?

We have been studying the kinetics of aromatic nitration on the lines indicated in a prefatory publication[1], and in consequence have an opinion to offer on the question indicated by the title, which has been raised more than once recently, notably in an interesting article by Kenner[2].

Any process of co-ordination between an atom with an unshared electron pair and another with an open sextet can conceptually be dissected into a univalent electron transfer and a succeeding homopolar union. It has not hitherto been usual to assume such a stepwise mechanism in the absence of some evidence of dimerization or other characteristic reaction of the radicals which would be formed intermediately. However, Kenner has proposed a representation which suggests that this evidential requirement can be obviated by supposing the radicals throughout their life to remain "within the sphere of each other's action". His nitration mechanism is expressed, for the nitration of benzene in the presence of sulphuric acid, in the following approximate manner (the brackets indicate 'spheres of action'):



Whereas Kenner's ideas undoubtedly have important applications, we think that, in this particular case, the assumption which might have accounted for the general absence of radical dimerization in aromatic nitration does not in fact provide a simple and entirely satisfactory escape from this and similar difficulties. The above scheme depicts three molecular encounters, and requires the nitrating agent to exist as nitrogen dioxide from the first to the third, that is, throughout the period in which the bisulphate ion and aromatic cation are finding, and reacting with, each other. The nitrogen dioxide molecule must be assumed to remain, during this kinetic transaction, continually within the 'sphere of action' of the aromatic molecule, though presumably bound therein by van der Waals forces only. This is not an easy assumption; and since the physical theory of such forces shows that they never exclude, or greatly interfere with, each other, one is caused to wonder why the nitrogen dioxide is prevented from being also within the 'sphere of action' of the solvent sulphuric acid, to which it will also be bound by van der Waals forces, and with which introduced nitrogen dioxide reacts to give products that are not formed under normal nitration conditions.

Our kinetic work does not suggest that the attack of a nitrating agent derived from nitric acid on an aromatic ring in liquid-phase nitration is ever anything but simply co-ordinative and heterolytic, as would be illustrated by telescoping Kenner's three steps completely, or at least so extensively as to render the step-wise representation an unsatisfactory approximation. The complete mechanism of this electrophilic substitution, including the preliminary formation of the nitronium ion, may, however, b 'unimolecular' or 'bimolecular', with appropriat kinetic differences[1], according as the heterolysis o the nitric acid molecule to yield the nitronium io NO_2^+ is rate-determining or not. The kinetics show that the unimolecular step which can become rate determining is a reaction of the nitric acid, and nc of the solvent (as we once thought) or the aromati substance; and, since it is too slow to be explaine as heterolysis of an OH-group (proton transfer), i must be interpreted as the heterolysis of an NO-bond necessarily to form nitronium ion.

It is by no means implied that univalent electro transfers[3], homopolar unions, and homolyses[4] neve play any part in nitration. We think our kineti results show that they have a role in nitrations by, or with the catalytic help of, nitrous acid. But it i probably relevant that nitrous acid can introduc odd-electron molecules into the system, notably nitrogen dioxide. All these matters will be mor fully discussed elsewhere.

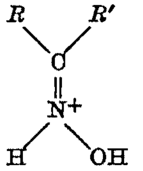
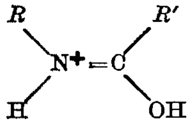
Mechanism of the Beckmann Rearrangement

Higman[1] recently suggested a new mechanism for the Beckmann rearrangement, which postulates that the cation (I) rearranges by rotation of the central $>C=N<$ unit through 90° to form (II). This suggestion, though ingenious, is not in accordance with the known facts.



(I)



(II)

The rearrangement of the toluenesulphonates[2] and picryl ethers[3] of ketoximes to derivatives of amides is not prototropic and proceeds by separation of the potential anion attached to nitrogen. The evidence on the latter point is quite unambiguous. The reaction is much faster in solvents of higher dielectric constant; electron-repelling groups (*R*,*R'*) accelerate the reaction, although such groups in other rearrangements (for example, pinacol-pinacoline) have a lower 'migratory aptitude'; the 2:4-dinitrophenyl ethers do not rearrange, though the picryl ethers do so readily. None of these effects would be expected on the basis of Higman's mechanism.

For the acid-catalysed Beckmann rearrangement equally definite evidence is available, and here the proton probably attacks oxygen and not nitrogen.

odskiĭ and Miklukhin[4] have shown that when nzophenone oxime is rearranged in aqueous hydroloric acid enriched with H_2O^{18}, complete exchange oxygen with solvent takes place. Benzanilide changes none of its oxygen under these conditions. erefore the oxygen atom in the resulting benzilide molecule is not the same one that was present the oxime. This is incompatible with Higman's echanism, unless a highly improbable oxygen exange takes place in the oxime itself. Such an change would involve inversion of configuration d formation of mixed amides, neither of which is served under the operative conditions.

All the known facts are well interpreted in terms the ionization mechanism which was lucidly set rth in the article[5] to which Higman referred. It difficult to see why that theory should now be ought unacceptable, and in point of fact no criticm of it has been advanced.

orphyrin Fluorescence in the Livers of ellagrins in Relation to Ultra-Violet Light

THE examination, by ultra-violet fluorescence icroscopy, of frozen sections of fragments of livers emoved by an improved biopsy procedure[1] from wenty African pellagrins, soon after admission to ospital, revealed the presence in eight cases of an ntense scarlet red fluorescence. This fluorescence was calized to the hepatic cells, and, when severe, could volve the entire lobule. When the fluorescent aterial was dissolved in the fat droplets in the epatic cells, these assumed an intense crimson colour.

In serial biopsies at weekly intervals of livers of hese eight pellagrins maintained on a carbohydrate itamin-poor diet, it was seen that this fluorescence isappeared first from the central zone and last from he periportal region of the lobules. In so doing, all radations of colours from red to yellowish-brown ackground fluorescence, previously described[2], were bserved.

Oxidized cytochrome, bilicyanin and porphyrins re, so far as we know, the only likely substances in nimal tissue said to give a red fluorescence[3]. We re satisfied that the scarlet fluorescence in the livers f pellagrins is not oxidized cytochrome or bilicyanin or the following reasons: (1) We obtained no uorescence in concentrated solutions of oxidized ytochrome prepared from beef heart by the method f Keilin and Hartree[4]. (2) Bilicyanin prepared by dding an alcoholic solution of zinc sulphate and dine to an alcoholic solution of bilirubin gives a ellow-red fluorescence which is rapidly changed to ellow-green on the addition of alkalis and, simulaneously, the spectroscopic bands characteristic of holetelin make their appearance. (3) The red uorescence of the livers of pellagrins is intensified y acids and alkalis. It is soluble in water and we ave found it, in this respect, to react in a manner entical to dilute solutions of protoporphyrin and he red fluorescence we observed in a liver obtained from a case of severe porphyria in a woman seen in the acute stages of the disease.

Unfortunately, the core of liver tissue obtained from pellagrins was too small to allow for the extraction of porphyrin for spectroscopic identification. The porphyrin fluorescence in the pellagrous livers was invariably associated with evidence of active formation of cytolipochrome and cytosiderin. The iron in some of these livers may amount to as much as 5 per cent of dry weight of liver[5]. The transitory character of the scarlet fluorescence appearing in the acute phases of the disease can easily account for the presence of masses of iron pigment so constantly present in the livers of pellagrins[5,6,7] without any visible porphyrin fluorescence.

The association of scarlet fluorescence and iron pigment is further evidence in support of our view that cytosiderosis of the livers of adult pellagrins is an expression of the disruption of an iron porphyrin complex within the liver cell.

Three pellagrins who had lost their porphyrin fluorescence while on a carbohydrate vitamin-poor diet were afterwards exposed to ultra-violet light for ten minutes on five consecutive days. When biopsy was performed on the sixth day, a marked recrudescence in the fluorescence was noted in the livers of all cases, and in two it was even more intense than on the day of admission to hospital; there was no aggravation of the skin lesions or of the systemic reactions generally seen in this disease. Traces of porphyrins were found in the urine of only one of these cases. Examination of the liver of a healthy patient, admitted to hospital for a minor surgical injury, before and after treatment with ultra-violet light under conditions identical to those provided for the pellagrins, revealed the absence of visible scarlet fluorescence.

From these studies we conclude: (1) Porphyrin fluorescence in the liver can occur during the acute phases of pellagra. (2) The great accumulation of iron pigment in many livers of adult African pellagrins is probably caused by the disruption of an intracellular iron porphyrin complex, such as catalase and cytochrome, present normally in the liver cell. (3) Treatment with vitamin B complex is not required to resolve the porphyrin fluorescence in the livers of pellagrins while on a carbohydrate vitamin-poor diet. (4) Ultra-violet light can excite a recrudescence of the porphyrin fluorescence in the liver without causing an exacerbation of the other external manifestations of the disease. Massive quantities of porphyrins can appear in the liver cells without any detectable amounts in the urine. (5) These experiments emphasize the close inter-relationship between the reactivity of the skin to ultra-violet light and the deposition of iron and the appearance of porphyrin fluorescence in the liver in African pellagrins.

Acetylphosphatase in Animal Tissues

IN the course of experiments on the metabolism of acetylphosphate in rats, an enzyme which catalyses the hydrolysis of this substrate was found. The enzyme is present in homogenates as well as in cell-free extracts of liver, muscle, kidney, brain, but not in blood serum. Acetylphosphate $M/20$ (prepared according to Lipmann and Tuttle[1]) was incubated with liver homogenate and sodium bicarbonate buffer (pH 7·3) at 38° C. More than 80 per cent cleavage was observed in five minutes, and total cleavage was obtained in fifteen minutes. The spontaneous cleavage of acetylphosphate in the same conditions but in the absence of liver was 33 per cent in 180 minutes. The enzyme activity was found to be of the same order of magnitude in extracts of liver, kidney, brain and muscle.

Some properties of the enzyme are described below. The experiments were conducted at 25° C. in order to slow up the action. The hydrolysis was followed (*a*) by estimation of the amounts of inorganic phosphate liberated, using the method of Lipmann and Tuttle[2], (*b*) volumetrically in terms of carbon dioxide formed in the presence of sodium bicarbonate, due to the liberation of acid equivalents during cleavage.

The activity of the extracts was completely destroyed by boiling for five minutes. Acetylphosphatase is relatively resistant to fluoride poisoning. No inhibition was observed with concentrations of $M/100$ sodium fluoride. $M/20$ sodium fluoride retarded the hydrolysis by 50 per cent (as measured by the amount of substrate hydrolysed after fifteen minutes). Sodium cyanide failed altogether to influence the enzyme activity even at concentrations of $M/10$. On the other hand, inorganic phosphate is strongly inhibiting. Inorganic phosphate appears to compete with acetylphosphate for the enzyme: thus, at a substrate concentration of $M/100$, a concentration of $M/30$ inorganic phosphate caused complete inhibition, whereas at $M/20$ substrate concentration an inhibition of only 60 per cent was obtained. Enzyme activity at this substrate concentration is completely annulled by $M/10$ inorganic phosphate, the hydrolysis proceeding at the same rate as in the absence of enzyme.

The non-identity of acetylphosphatase with ordinary 'alkaline' phosphatase is shown by the different distribution of these enzymes in organs and their different behaviour with poisons. The presence of a highly active acetylphosphatase in animal tissues suggests an explanation for negative results obtained with the use of this substrate for phosphate transfer[3] and acetylation[4] in animal tissues. It seems probable that when acetylphosphate is added to animal tissues it is removed by hydrolysis before its possible action as a phosphate or acetyl donor can become manifest. When acetylphosphate appears as an intermediate in metabolism, it is probably maintained in an adequate steady-state concentration within the tissue because the action of acetylphosphatase in these conditions is retarded by inorganic phosphate.

An Attempt to Obtain Nuclear Excitati by Means of X-Rays

WHEN a substance is irradiated with γ-rays of energy less than that necessary for disintegrati of the nuclei (for most of the elements about 8 MeV only a nuclear excitation can take place. If rad activity is obtained by such an irradiation, it necessary to assume the existence of isome metastable states to which the nuclei have be excited and from which transitions to the groun level take place by emission of (highly converte γ-rays. Experiments in this direction were perform in 1939 by Pontecorvo[1] and Collins[2]. They succeed in activating indium by means of X-rays with energy of more than 1 MeV. By direct irradiation eleven elements, Trumpy[3] later claimed to have asce tained the existence of thirty-five new isomer nuclei with characteristic half-life periods. By varyi the tube voltage from 300 to 1,800 kV., Trumpy w able to determine the critical excitation energy wi an accuracy of 10 per cent. The values we surprisingly low and in fourteen cases less tha 0·4 MeV.

With an X-ray tube supplied from a high-tensi equipment for a 400 kV. maximum, I have irradiate aluminium, copper, rhodium, silver, cadmium, indiun tin, gold and lead. As the radiation emitted by th transition to the ground-level must be assumed to b rather weak, the counters are made of the eleme which is under investigation. In some cases, howeve the substances (in the form of thick foils) have bee investigated inside a specially constructed count where the radiation from the active substance is onl absorbed by the gas in the counter chamber.

The X-ray tube has worked at 390 kV. (max.) wit a tube current of 5 mA. (max.). The anti-cathod is of tungsten and in the shape of a disk, so tha about half the current is reflected backwards.

On the irradiation of copper, rhodium, cadmiun indium, tin, gold and lead, activity has in no cas been observed. With a Geiger-Müller tube of aluminiu made four years ago, a weak effect of the same orde of magnitude as the zero effect was observed, th activity decreasing with a half-life period of abou 2–3 min. Freshly made tubes or foils of aluminiu do not show this effect. A Geiger-Müller tube o glass with a cathode of silver also showed a wea activity of the same intensity as the aluminium tube

The negative result with rhodium is especiall interesting as the nucleus ^{103}Rh is excited by irradiation with fast neutrons[4] to an isomeric state of th stable nucleus and situated only 19 kV. above th ground-level. For such an element, according to ou present conception of the formation of isomeri nuclei by high-voltage X-rays, the activation level might be expected to be situated nearer the ground level than is the case when the lowest metastabl state lies, for example, 200 kV. above the ground level.

At the present stage, when the voltage of the tub cannot be increased, it can only be said that, wit the intensity and energy of the X-ray quanta use here, no activation levels can be found in the element named above. As pointed out by Wiedenbeck[5] an Northrup *et al.*[6] special care must be taken in investigations with irradiated Geiger-Müller tubes Sherrer[7] has shown that in special circumstance field emission of electrons can take place from th Geiger-Müller tube cathode surface, thus falsifyin an induced activity. It seems probable to me tha e excitation levels with low energy ($<$ 400 keV.) und by Trumpy may be of such non-nuclear origin.

se of Growth-Promoting Substances in he Prevention of Apple Drop following Frost

EXPERIMENTS both in the United States and at ong Ashton Research Station have shown that cer-in substances, when suitably compounded and pplied, will induce the parthenocarpic development f the tomato and other fruits. These fruits are, of urse, seedless. The banana, Washington Navel range, and seedless grapefruit are examples of fruits hich are naturally parthenocarpically produced. nce, in Nature, some fruits may be found which re seedless, it follows that, given an understanding f the natural process, it should be possible to pro-uce seedless fruits of almost any species. This has, n fact, now become an established commercial prac-ice in the tomato. The materials and methods em-loyed in Britain have already been published[1].

Similar experiments with apples and pears were arried out at Long Ashton in 1943 and 1944 and y other workers in the United States, but without uccess. At Long Ashton, certain compounds were artially effective in that they did cause the fruit o remain on the trees until July, when they fell off.

The severe frost of April 30–May 1, 1945, when ost of the apple blossom had set and the fruitlets ere already beginning to grow, killed the embryos nd blackened the centres of all fruits. This provided unique opportunity to try a number of compounds elected after recent experience with tomatoes.

Two varieties of apple were selected for trial, amely, Miller's Seedling and Cox's Orange Pippin, oth about eighteen years old and carrying a heavy et of fruit. Six trees in each row were sprayed ith a wash containing beta indole butyric acid, lpha naphthalene acetic acid, 2–4 dichloro phenoxy cetic acid and beta naphthoxy acetic acid at 5, 5, 5 nd 60 p.p.m. respectively, making a total hormone oncentration of 75 p.p.m. The choice of these aterials and concentrations was based upon a wide xperience of their use in the production of partheno-arpy in the tomato.

The wash was applied by a power sprayer using a ressure of 400 lb./sq. in. The day was reasonably alm, and each tree was thoroughly drenched with bout ten gallons of wash per tree.

The results were spectacular. Within fourteen ays almost every fruit had fallen from the unsprayed trees of Miller's Seedling, whereas none had llen from the sprayed trees. Furthermore, these uitlets had begun to swell. The spray also caused a onsiderable amount of leaf epinasty.

In contrast to the above effect upon Miller's Seedling, the spray had no effect whatsoever upon Cox's Orange Pippin. There was not even epinasty of the foliage and every fruit fell.

Observations were continued throughout the summer of 1945. By July 14 practically every fruit had fallen from the unsprayed trees of Miller's Seedling, but the fruits were literally clustered on the treated trees. Many of these fruits had grown to about a quarter normal size, but had ceased further development, so it was decided to thin some of these trees. During this operation it was found that the fruit tended to break away from the spur anywhere along the fruit-stalk rather than at the abscission layer, which was very firm indeed. By this date most of the fruits were about 1¼ in. in diameter and were noticeably sweet and juicy.

Final observations were made on August 14 when the crop was picked except for two trees which were left as specimens. By this date the fruit was fully ripe and ready to harvest, but showed no tendency to drop even when the trees were shaken vigorously, whereas the few fruits which remained on the control trees had started to drop.

The effect of the treatments is shown in the accompanying table.

MEANS PER TREE (MILLER'S SEEDLING)

	Weight in lb.	No. of fruits more than 2 in. in diameter	No. of fruits 1¼–2 in. diameter	No. of fruits less than 1¼ in. in diameter
Treated :				
Unthinned	169	13	621	9,486
Thinned	60	30	325	2,025
Control	17	29	88	443

The extraordinary effect of the spray in keeping the fruit on the trees is shown by the fact that the unthinned trees had an average of 9,486 fruits per tree. Because of war-time difficulties it was not possible to thin these trees early enough to produce any really advantageous effects; but even when thinned as late as July 14, the effect is seen in the number of fruits which were graded 1¼ in.–2 in. diameter.

So far as I am aware, this is the first time that any success has been obtained in preventing the fall of deciduous fruit by means of growth-promoting substances. It is admitted that the result is not at present of immediate practical or economic importance; but it is now only a matter of time before suitable materials and methods will be evolved for this purpose.

The complexity of the problem is indicated by the fact that materials which proved highly effective on Miller's Seedling were without any effect upon Cox's Orange Pippin. The specific nature of many of the growth-promoting substances is, of course, well known, and this serves as a particularly good example.

This preliminary trial has also revealed certain points of practical importance. The amounts of substances used were undoubtedly excessive, and in our endeavour to get a complete cover we used too much wash per tree. This is indicated by the fact that the 'buffer' trees which received only the spray drift set a fair crop and neither the foliage nor growth was adversely affected. The heavy application of the growth hormone mixture to the Miller's Seedling trees suppressed the 1945 extension shoot growth, so that these trees had a much lower leaf area during the 1945 growing season than had the control trees. This suppression of shoot growth is in itself an undesirable effect, and in these trees may cause a lowered flower production both in 1946 and 1947.

Since this trial was initiated, other substances have been brought to my notice, and these may be even more effective on apples and pears than the ones used above. Furthermore, the success obtained with tomato flower extract and animal sex hormones as recently reported by me[2] offers still further scope for development along these lines.

Accumulation of Sugars in Barley Seedlings on Very Acid Soil

FOR a number of years it has been noticed at Woburn that seedling barley plants sown in soil too acid to allow normal growth (*p*H 4·3 or thereabouts) were very much more attractive to small birds (chaffinches and the like) than similar seedlings grown on a normal soil (*p*H 6·0–6·5); and that consequently a very large proportion of the growing seedlings were dug up and the seeds eaten when little or no similar damage was done to plants on normal soil. At first the tendency was to attribute the difference to the slowness of growth on the acid soil, which kept the seedlings in a condition suitable for bird attack for a much longer period, but this explanation failed when it was found that the seedlings were attacked almost as soon as the shoots appeared above the ground.

It seemed certain that the seedlings on the very acid soil contained something which made them more attractive to birds, and it was suggested that there might be an accumulation of sugars which made them much sweeter than normal plants at the same stage of growth. We have now examined on several occasions seedlings from both types of soil, grown on trays under similar conditions to the point when the second leaf was just visible, when they are still quite attractive to birds. This stage was reached with normal soil in 11–15 days, and with the very acid soil in 19–21 days. The plants were then pulled up in the morning, the fibrous roots cut off, the seeds and the tops separated from one another and the total sugars soluble in alcohol determined with Fehling's solution after inversion with acid.

The results obtained in two separate experiments are shown below, the percentages being on the dry matter of the tops or the seeds.

GLUCOSE EQUIVALENT OF TOTAL SUGARS

	Normal soil (*p*H 6·5)		Very acid soil (*p*H 4·2)	
	Tops	Seeds	Tops	Seeds
a	5 3 per cent	26·8 per cent	24·1 per cent	42·6 per cent
b	7·2 ,,	21·1 ,,	29·7 ,,	30·6 ,,

It is clear, therefore, that there tends to be an accumulation of sugar both in the tops and in the seeds where the seedlings are grown on very acid soil, probably due to the feeble growth of the seedlings after germination has taken place.

The cause of the attractiveness to the birds is still better shown if the figures are given as sugar (that is, glucose equivalent) per 100 tops or seeds. These are as follows:

GLUCOSE EQUIVALENT OF TOTAL SUGARS PER 100 TOPS OR S

	Normal soil (*p*H 6·5)		Very acid soil (*p*H 4·	
	Tops	Seeds	Tops	Seed
a	56 mgm.	457 mgm.	178 mgm.	984
b	59 ,,	348 ,,	298 ,,	700

Acoustic Control in the Flight of Bat

PROF. HARTRIDGE has suggested[1] a compari between radar and acoustic range- and directi finding in bats. He suggests that the interrup supersonic note may be used to measure the ra to obstacles. The note emitted lasts about 0·01 During this time the first waves of the sound travel about 10 ft. To determine range with accuracy either the onset (leading edge) or the end (trailing edge) of the echo must be used as a pc of reference.

If it is assumed that a bat, like a radar set, u the leading edge of the echo to judge range, the le range which it could perceive would be consideral In a radar equipment with a 1 µsec. pulse the lead edge of the echo from an object at less than metres from the aerials will be received during period of transmission and therefore lost. For a there will be a similar range blind to the leading e of about 5 ft. It is possible that the bat uses trailing edge of the echo, however. In these circu stances there will be no well-defined lower limit range measurement. One function of the comp intra-aural muscle reflex may be to make use of trailing edge, for without this the reflected n from close objects would appear to the bat as c tinuous with the emitted one. In natural conditic the eyes no doubt also assist in perceiving n objects.

The maximum range at which an object can detected may also be limited. In an airborne rac equipment which is so designed that the outgoi signals are not beamed, the maximum range at wh an aircraft can be detected is equal to the heig of the radar equipment. This is because the sign reflected from the ground tend to swamp all othe It is possible that the bat overcomes this difficul by the great development of the pinnæ of the ea which may allow it to hear only echoes from obje directly ahead.

D. W. EWER.

Great Missenden,
Bucks.
Nov. 4.

---

[1] Hartridge, H., *Nature*, 156, 490 (1945).

DR. EWER has raised an interesting point w regard to bats' hearing which I have been trying elucidate. We have been approaching the mat from somewhat different points of view. There very strong evidence that bats are aware of obstac ahead of them not only when they are several met away, but also when they are quite close. Th during my experiments in King's College in 19 these animals were observed to fly quickly throu an open doorway from one room to another. the intervening door was gradually closed to hes, fewer passed through and there was a good al of fluttering before the passage was negotiated. the door was closed to four inches, the bats would it were come up and look and then fly off again thout attempting to pass. This experiment was eated with all lights extinguished, and it was found at many bats negotiated the six-inch opening ough always with much audible fluttering; larger enings than this they swooped through without ncern. This fact was found by closing the light itch suddenly and catching one on the point of tering or emerging."

Galambos and Griffin, who investigated the cries bats with a supersonic detector, reported that "the personic cry lasts no more than 0·02 second on e records, and there is good reason to believe that ertial factors in the recording device introduce rors into this estimate. The cry probably lasts no ore than 0·01 second." Now it is clear, if this timate be correct, that a bat two metres away from reflecting object should be able to hear the whole the echo without any interference from the sound hich it is emitting from its larynx. As it flies towards e object, however, more and more of the echo incides with the period of sound emission, thus terfering with the hearing of the echo. There are ree possible ways of avoiding this difficulty: to ake use of the Doppler effect, to shorten the period f sound production and to screen the ears from the urce of sound. With regard to the first way, a at flying at 3 metres per second towards an object ould hear an echo exceeding the pitch of its voice y about one fifth tone. The human ear would be ble to identify this change of pitch; but it is very oubtful whether it would be able to detect the xistence of such an echo when a strong voice tone as present at the same time. A similar statement may e made about a bat. But an even more important oint is that when a bat slows up, and starts to flutter, s it approaches an obstacle, the Doppler effect disappears and the echo more and more resembles the oice tone in pitch.

It has been shown by Galambos and Griffin that the umber of supersonic cries made by a bat depends n where it is and what it is doing. A resting bat sually produces 5–10 cries per sec. When it begins fly, the number increases to 20–30. When it is pproaching an obstacle it may produce 50–60 per c. But as soon as it has passed the obstacle, the umber drops abruptly to 20–30 again. Now it is ossible, as the number of cries per second is increased, at the duration of each cry is correspondingly duced. If such were the case, then overlap between e echo and the voice might be avoided as an bstacle is approached. The following table shows r different distances the maximum duration of the y if overlap is to be avoided.

Distance	Duration (0·001 sec.)
200 cm.	12
100 ,,	6
50 ,,	3
25 ,,	1·5
16 ,,	1

uch short durations are not impossible in view of alambos and Griffin's statements concerning their upersonic detector.

With regard to the screening of the ears from the oice tone, I am told that bats can be divided into wo groups: those with flat snouts and normal ears, nd those with the usual pointed snout but having a ecially developed cartilage, the tragus, in front of the external auditory meatus. The flat snout, by directing most of the supersonic energy in a forward direction, may screen the ears and thus enable them to pick up faint echoes. The tragus in the other group of bats may have the function of screening the ears from the direct voice tone while it permits the entrance of reflected sounds.

With regard to Dr. Ewer's suggestion that it may be the trailing edge of echo which the bat uses for localizing purposes, I think it is more likely to be the leading edge that is used because the former is liable to be masked by sounds reflected by other objects in the vicinity. It is quite possible that the bat uses both leading and trailing edges of the echo for localizing purposes.

H. Hartridge.

WITH reference to the interesting article on bats by Prof. H. Hartridge in *Nature* of October 27, p. 490, I venture to submit certain observations made by a group of observers without professional scientific qualifications but with some theoretical and practical knowledge of aviation. The group in question consisted of three pilots and two gunners at a Royal Air Force camp in Italy. Our admiration was roused by the performance of a large number of bats that infested our camp soon after dark each evening.

Though we had no knowledge of the acoustic control system of bats described by Prof. Hartridge, we soon came to the conclusion that something of the sort must be employed. The room from which we made these observations was a lofty one with a very large area of french windows; when the electric light was on, the glass of these windows was entirely invisible from outside. The bats, apparently attracted by the light, would turn and dive repeatedly at these windows with the obvious intention of passing inside the room. They invariably detected the presence of the glass, however, and never once did they crash into it. This seemed the more remarkable as birds had occasionally been deceived in broad daylight; the open appearance of the room, which was comparatively narrow, with windows on both sides, encouraged them to attempt to swoop right through it, with disastrous results.

Detection seemed to occur about two feet from the glass, which left very little room for avoiding-action. This usually consisted of a steep turn to starboard, but we observed many stalled turns, and, much to our astonishment, half rolls! Since we had all been under the impression the latter manœuvre was unheard of in Nature, we took some trouble to confirm it. As the bat approached to within two feet of the glass, it would fold up its starboard wing, but keep the other extended; the unequal lift turned it on to its back in a flash, whereupon it extended both wings and fell vertically down the surface of the glass at a distance of a few inches, pulling out on a reciprocal course some three or four feet lower down. We confirmed this by watching from inside the glass where, in these cases, we had a clear, though very brief, sight of the bat with its belly and the underside of its wings presented to the glass and its head pointing straight downwards.

I think it possible that anyone making a serious study of a bat's manœuvring ability might find this method of observing at night from behind a brightly illuminated glass barrier extremely useful.

Martin Wilkinson.

Nov. 13.

MEDAL AWARDS OF THE ROYAL SOCIETY

Copley Medal

THE Copley Medal is awarded to Dr. Oswald Theodore Avery, of the Rockefeller Institute of New York, for his contributions to knowledge of the chemical basis of the specific properties of bacteria, particularly of the types of the pneumococcus. His researches in this field have appeared in unhurried and orderly sequence over the course of a long and distinguished career, and they have furnished a large and essential constituent of the framework now available for a fundamental science of immunochemistry.

We allow ourselves to claim Avery as Canadian by birth, though with acknowledgment that his life's work has been accomplished in the United States of America, and in the Rockefeller Institute of New York in particular, of which he has held the membership since 1913.

It was in 1917 that Dochez and Avery demonstrated that cultures of different strains of the pneumococcus yielded different 'soluble specific substances'. From 1923 onwards, appeared a remarkable series of papers by Avery, with Heidelberger and other collaborators, in which it was shown that these specific substances had the nature of complex polysaccharides of highly individual characters. These were present in the regular capsular envelope characteristic of the pneumococcus in its virulent forms ; and each type of such virulent pneumococci, distinguishable by its immunological specificity, was shown to have its own distinct polysaccharide. Each of these reacted, with a like specificity, with the corresponding immune body. Not that these polysaccharides, the soluble specific substances isolated in chemical purity, had antigenic properties by themselves. It was only when they were artificially linked to proteins foreign to the reacting animal body, or retained their natural linkage with proteins of the bacterial strains producing them, that they elicited, on injection, the appearance in the blood of specific immune substances, causing agglutination or lysis of the corresponding organisms ; but, with the immune substances thus evoked, the pure, separated polysaccharides now exhibited the same specific affinities, each forming a precipitate with the corresponding antiserum.

Here, then, in chemically definite form, were separable, prosthetic, combining groups such as Paul Ehrlich had long earlier envisaged and prophetically named 'haptenes'. Here also was one of the principal foundation stones of a great building of immunological chemistry, which, in the hands of Avery's contemporaries and followers, notably in those of a distinguished fellow-member of the Rockefeller Institute, the late Karl Landsteiner, has rapidly included an ever-widening range of studies of artificial and natural antigens.

Meanwhile, in the hands of Avery and his coworkers, knowledge of the specific characters of the pneumococci, and of the manner in which these are acquired, had been moving quietly to a new pinnacle of achievement. They had long ago shown that pneumococci, which, in artificial culture, have lost the capsules endowing them with virulence and containing the specific polysaccharides, have reverted to avirulent non-specific types, growing in the rough, wrinkled colonies characteristic of such defective strains. It had been shown also, by the late F Griffith, that such a degenerate, non-specific pn mococcus, from whatever specific type it had provenance, could be induced by cultivation in medium prepared from a complete, virulent type re-acquire a capsule conferring the correspondi specificity. And now, only last year, Avery, w Macleod and McCarty, has been able to isolate and characterize a chemical principle acting in mini dosage as the specific stimulus to such a transformati An unencapsulated, avirulent, typeless pneumococ derived from a specific strain of type II responds this stimulus by acquiring and retaining the caps and specific polysaccharide, with the virulence a the cultural characters, of a fully specific strain type III. Here surely is a change to which, if were dealing with higher organisms, we should acc the status of a genetic variation ; and the substar inducing it—the gene in solution, one is tempted call it—appears to be a nucleic acid of the desoxy bose type. Whatever it be, it is something whi should be capable of complete description in ter of structural chemistry.

Avery, a veteran now among investigators, h thus, on the eve of his retirement, attained this ne peak of discovery—a fitting climax to a devot career of such wide influence on the progress science.

Royal Medals

A Royal Medal is awarded to Prof. John Desmo Bernal, professor of physics in Birkbeck College, U versity of London, in recognition of his distinguish contributions to the theory and the applications X-ray crystal analysis.

Bernal's first important work in this field, publish in 1926, was a fundamental study of the basis of t interpretation of X-ray rotation photographs single crystals ; and the methods which he th evolved are still in use. He was largely concern with the initiative which led to the construction the "International Crystalline Tables", and hims accepted an important share of the editorial wo required. Later he became a leader in the applicati of X-ray crystallography to the elucidation of t structure of highly complex organic molecul Organic chemists had encountered difficulties, lo insuperable, in formulating a satisfactory structu for the sterols. Here Bernal's crystallographic dat indicating the general shape and dimensional limi of the sterol molecule, supplied a key which open the way to a convincing reconstruction of the pol cyclic framework of cholesterol, ergosterol and cal ferol in the first place, and eventually to the stru tural formulation of a vitally important series gonadal and adrenal hormones, as these, in d course, were isolated and identified. With admirab enterprise he, with his pupils and associates, pr ceeded to apply the methods of X-ray crystall graphy to crystals of some of the simpler protein as these became available, such as crystalline peps and, later, insulin. Then the discovery, by Stanle that a plant virus—that causing the 'mosaic' diseas of tobacco—could be obtained in crystalline for opened the way for Bernal to apply his techniq to elucidate the structure of a protein endowed wi such paradoxical characters. He was able to descri the virus units as long, rod-like structures, 1,500 ength by 150 A. in diameter, and with an inner larity in structure fitting a hexagon lattice and, arently, consisting of cubical sub-units measuring ut 11 A. The readiness with which the long virus ts, in a solution, set themselves parallel in a two- ensional lattice provided an explanation for the ble refraction and other physical properties which h solutions of the virus exhibit.

ust before the War, Bernal had published a pre- inary note on the structures of hæmoglobin and chymotrypsin. Then, like others, he found his ivities diverted to the scientific service of the cial needs of the nation and its allies at war. The e is not yet for detailed mention of the important cial researches he has carried out during the years mediately past, for the Ministry of Civil Defence, Combined Operations Command, and other vice Departments, which have successively made ims on his special knowledge and ability. We are d to know that some of his pupils have been able keep the thread of his more normal scientific tivities unbroken over this interval. Biochemistry, well as the physics of his primary discipline, will pect much now from his resumption of personal rticipation and leadership in a field which he has de so much his own.

A Royal Medal is awarded to Dr. Edward James lisbury, director of the Royal Botanic Gardens, ew, in recognition of his distinguished contributions plant ecology.

Salisbury's work has had a most important influence broadening the basis of the study of British plant mmunities, and in diverting ecological work in eat Britain from an essentially floristic outlook to e in which the habitat and the autecology of in- vidual species have been put in the forefront of terest.

Combining his expert ecological knowledge with a ide acquaintance with cultivated plants and their nditions of growth, Salisbury has shown an ex- ptional capacity for relating horticultural practices known physiological and ecological facts, where more strikingly shown than in his "Living arden". A similar faculty served the country well the earlier part of the War in connexion with his anifold activities on the Agricultural Research ouncil.

Making his first contacts with ecology by a de- iled study of the oak-hornbeam woods of Hertford- ire, to which he brought some of the experience ined by co-operation with F. W. Oliver in the vestigation of the maritime communities at Blake- ey Point, Norfolk, Salisbury soon exhibited a more neralized approach to ecological problems. Ex- mples are furnished by his papers on the calcicolous abit and on leaching, which traverse a wide field nd open up new points of view. Although somewhat ifferent in scope, the investigation on stomatal fre- uency, supported by a very large mass of data and ublished in the *Philosophical Transactions* in 1927, essentially directed to clarifying the ecological icture.

In his presidential address to the Ecological Society 1929 on the biological equipment of species in elation to competition, a topic which is repeatedly ouched upon in his earlier work, attention was irected to the almost complete lack of information on he reproductive efficiency of the different species of lowering plants. This aspect of a species' equipment ad already interested Salisbury for some years, and a number of significant data were given in the course of his address. Despite preoccupation with many other matters, he continued actively to accumulate information on reproductive capacity during the subsequent years, collecting data on the seed production of more than 240 British species, which involved the examination of several hundreds of thousands of individual plants. The numerous important conclusions derived from this comprehensive study, which disposes of several fallacies, were published in 1942 in a book, "The Reproductive Capacity of Plants", which constitutes a landmark in the progress of plant ecology.

In addition to his ecological work, Salisbury is known to his botanical colleagues for earlier work on fossil seeds and for important contributions to the distribution of British plants and to the interpretation of floral morphology.

Davy Medal

The Davy Medal is awarded to Prof. Roger Adams, professor of chemistry in the University of Illinois, in recognition of his distinguished researches in organic chemistry.

Roger Adams is undoubtedly the outstanding organic chemist in the United States at the present time, and his school, the largest and most vigorous of its kind in that country, is of international repute.

His researches, distinguished by great originality and dogged perseverance alike, embrace a remarkably wide field. In a series of brilliant papers he has described the complete elucidation of the structure of gossypol, a highly complex pigment present in cotton seed. This achievement is all the more noteworthy since several other investigators had failed to make much headway in examining this highly sensitive compound. His experimental skill and theoretical insight have, in recent years, led to notable advances in alkaloid chemistry, and in this connexion special mention may be made of his work on the structure of monocrotaline, the toxic constituent of various Crotalaria. Adams has been responsible for pioneering research in attempts to find synthetic substances antagonistic to the leprosy bacillus and other acid-fast bacteria, and this led him to a detailed study of the chemistry of hydnocarpic and chaulmoogric acids. He has contributed notably to our knowledge of the constituents of *Cannabis sativa* and *C. indica* (marihuana and hashish), and he has determined the structure of some of their major physiologically active components. His wide interests are clearly exemplified by his researches on stereochemical problems, particularly of the phenomenon of restricted rotation, where his work, especially with diphenyl derivatives, and more recently with aryl olefines and arylamines, is of fundamental importance. Another indication of his versatility is to be found in his detailed studies of catalytic hydrogenation with noble-metal catalysts; the platinic oxide catalyst which he perfected is now universally employed and is known as Adams's catalyst.

While Adams's researches place him in the first rank of contemporary organic chemists, his share in inaugurating the publication of "Organic Syntheses", and "Organic Reactions", immensely valuable standard works of an original type, has ensured that future generations of chemists will ever remain in his debt.

During the War, Adams's activities have been largely transferred to administrative spheres, where his foresight and organizing ability have enabled him to play an important part in the vast scientific effort of our American colleagues.

Hughes Medal

The Hughes Medal is awarded to Prof. B. F. J. Schonland, director of the Bernard Price Institute of Geophysics, University of the Witwatersrand, in recognition of his important physical studies of atmospheric electricity and thunderstorms.

Schonland's main contributions to physical research have been in the field of atmospheric electricity, and have dealt particularly with the complex series of electric discharges which constitute a 'stroke' of lightning. Although the study of phenomena associated with thunderstorms could be undertaken under especially favourable natural conditions in his native South Africa, it needed enthusiasm and perseverance to overcome the many technical difficulties encountered in a country in which physical research had not yet been greatly developed, and to bring the research to such definite and illuminating conclusions.

Schonland's early work (1927, 1928) dealt with the polarity of thunderclouds; it was established that the negative was below the positive pole of the thundercloud, and that the currents flow in such a direction that they carry negative charges to the earth. Schonland also studied the importance of point discharges (from trees, etc.) in the maintenance of the earth's negative charge. He next used (1934–38) a rotating lens camera of the type devised by the late Sir Charles Boys to photograph and analyse the lightning discharge, and obtained results of great importance for knowledge not only of the nature of the lightning discharge but also of electric discharges in air in a more general sense.

Schonland has taken an active part in the study of cosmic radiation and particularly of the relation between penetrating radiation and thunderstorms; there is a reduction in the intensity of penetrating radiation when thunderclouds are overhead, and this fact provides information as to the total charge carried by penetrating radiation. The occurrence of impulses in a Geiger-Müller counter coincident with discharges in distant thunderstorms shows that some type of penetrating radiation is produced by electrical discharges during thunderstorms. This work on cosmic rays in Schonland's laboratory is of special importance, since few such systematic observations have been continued over long periods in the southern hemisphere.

Schonland has also taken a prominent part in the study of the nature of the 'atmospherics' interfering with wireless transmission, and of the part played by the ionosphere in their structure. These studies have equipped him on the technical side for various military positions he has held during the War; for these, also, his experience in the War of 1914–18 as a captain in the Royal Engineers (Signals) had given him additional equipment. In the War now ended he rose to the charge of an Army Operational Research Group with the rank of brigadier, and later became scientific adviser to the 21st Army Group commanded by Field-Marshal Montgomery; and now General Smuts, as Prime Minister of the Union of South Africa, has claimed Dr. Schonland's services as his adviser on the promotion and development of scientific research in his own country.

BOSE RESEARCH INSTITUTE, CALCUTTA

ANNUAL REPORTS

THE annual report of the governing body of
Bose Research Institute, Calcutta, for the y
1943–44 refers to the way in which the growi
difficulty in securing photographic materials, gl
goods and chemicals, especially organic chemica
hampers the work of the Institute. With gra
received from the Board of Scientific and Industr
Research, schemes of research on the setting up o
powerful generator of ultrasonic waves and
testing and cutting quartz plates for the radio indust
have been undertaken, and with grants from t
Bengal Immunity Co., Ltd., schemes for appli
research in microbiology and on the vernalization
paddy in Bengal are also being undertaken. Amo
the investigations referred to in the report are th
on cosmic rays, and an important paper on t
Wilson chamber study of meson spectra has be
published in the *Transactions* of the Institute, resu
obtained in the laboratory agreeing with the p
dictions of the theory of Moller and Rosenfeld. T
investigations with the Wilson chamber photograp
are being continued to verify and extend the resul
obtained with lead absorbers with other absorbe
like iron and carbon. Other physical researches we
concerned with nuclear fission, the nuclear isomeriz
tion of Br^{80}, the construction of a neutron generat
and an ultrasonic generator. A valve tube amplifi
circuit has been assembled for measuring dielect
potentials set up in plant tissues, either simultaneous
or under stimulation, and the transmission of excit
tion in *Nitella* and *Chara* is being studied.

An important part of the activity of the Bi
chemistry Department is the preparation of biologi
ally active compounds required for physiologic
and microbiological studies of plants, including su
substances as glucose 1-phosphate, adenylic ar
nucleic acids, *cis*- and *trans*-crocetin dimethyl este
crocin and picrocrocin, and it has been possible
isolate *cis*- and *trans*-crocetin dimethyl ester, croc
and saffranol from saffron obtained from Kashmi
the yields of these compounds from the Indian variet
being higher than those obtained by Kuhn ar
Karrer from saffron from Spain, the south of Fran
and Asia Minor. A series of manurial experimen
has been conducted with jute plants, and furth
investigations completed on the effect of the *p*
values of nutrient solutions on the growth of ju
plants.

In the Biology Department preliminary exper
ments on the auxin effect on *Desmodium gyran*
indicate that at low concentrations the auxin is
respiratory catalyst for some substrates present in th
cells of *Desmodium gyrans*, and that malate is one
the substrates on which this auxin acts. Differe
concentrations of synthetic auxin were tried to pr
duce roots in gootes and cuttings of cinchon
indolylbutyric acid being the most effective in th
formation of roots. The study of the growth of th
root is being carried out by an automatic recordin
device previously constructed in the Institute. In th
Microbiology Section, studies of the diseases
tropical fruits and vegetables are being undertake
to discover the nature of the relation between th
parasites and their specific hosts, nature of infectio
and mechanism of rotting, factors influencing th
susceptibility of fruits and control of wastage.

cial retting substance named 'Hiparol' has been covered which is capable of retting jute, coco-nut d other fibrous plants in 8–18 hours instead of the 0 weeks in the natural process. Strains of various cies of *Penicillium* have been isolated and their wth-rates and rates of production of penicillin died in modified Czapek-Dox and other media. ese investigations on penicillin and yeast are being tinued under a grant from the Bengal Immunity ., Ltd.

n the report for the year 1944–45, reference is de to the working out of a theory of the mechanism enzyme action, based on the assumption of differtial catalysis for reversible enzymic processes, d the preliminary, indications on the possible istence of two different phosphorylases in potato ve been confirmed. Other investigations have lated to the chemical transmission of stimulation d the problem of vernalization and the phasic velopment of some Indian crops, including wheat d paddy, and breeding work on cotton. The enzyme mplex, hiparol, is also capable of yielding butanol d acetone when mixed with suitable substrates, d the industrial application of this result is being vestigated. A strain of *P. notatum* isolated from cal garden soil possesses certain advantages over rains imported from abroad. Large-scale production the antibacterial agent is being undertaken; the ude filtrate is being used for surgical dressings on ses of *Staphylococcus* infection with very satisfactory sults.

RECENT CHEMICAL RESEARCH IN THE U.S.S.R.

SEVERAL chemical journals from Soviet Russia have recently been received, and a few of the any interesting papers in them may be briefly entioned.

Kapustinsky[1] has modified his well-known equation r the lattice energy of an ionic crystal by assuming n exponential equation for the repulsion force (Born–Mayer) instead of an inverse power law. The equation hen becomes, in k.cal.mol.$^{-1}$,

$$E = 287{\cdot}2\,\Sigma n\;\frac{z_1 z_2}{r_1 + r_2}\left(1 - \frac{0{\cdot}345}{r_1 + r_2}\right),$$

here Σn is the number of ions in the molecule, $_1$ and z_2 are the valencies, and r_1 and r_2 the radii f the ions. The calculated values are compared with those determined by the Born cycle method nd the discrepancies do not as a rule exceed 1 or per cent. The new equation is only slightly more omplicated than the older one, and comprises the ame variables: it is likely to prove of service in he study of ionic crystals.

Zvektov and Sosnorsky[2], by studying the dielectric roperties of an anisotropic liquid (liquid crystal) n a rotating magnetic field, measuring the torque xerted on the substance, have extended the work f Zvektov[3] to several other liquids. The results rovide a measure of the specific diamagnetic anisoropy, that is, the difference between the susceptiilities parallel to and perpendicular to the axis of ymmetry. It had previously been shown that the ffect is due to the single molecules and not, as was nce assumed, to molecular clusters. The effect is articularly marked in aromatic derivatives, and is n agreement with Pauling's view that in the benzene ing three of the four valency electrons of carbon have orbits in planes uniformly distributed in space while the orbit of the fourth lies in the plane of the ring. The implications of this are fully discussed, and the general assumption that the magnetic anisotropy of the liquid crystals examined is determined by the number of benzene rings in the molecules is, on the whole, substantiated.

The mechanism of the combustion of carbon in oxygen has been studied recently by several investigators. Klibanova and Frank-Kamenetzky[4] point out that the mechanism of reaction at ordinary pressure is quite different from that under very low pressures. It appears that at ordinary pressure at about 600° the surface of carbon in contact with carbon dioxide is covered with a film of surface oxides, CO and CO_2, and oxygen reacts with these much more easily than with a free carbon surface. At very low pressures, these surface oxides are absent. A difficulty in the kinetic measurements is that, in most cases, only the diffusion velocity is measured. In the present experiments, carbon filaments with a smooth deposited layer of crystalline carbon were used. The filament was electrically heated in a current of air or gas. The absolute reaction velocity was measured with oxygen (10^{-4} moles/cm.^{2} sec.), and the order of reaction was found to be much lower than unity, varying from 0·4 to 0·8, the usual assumption of a first-order reaction not being confirmed. The deviation from unity is regarded as applying to the true order. Theory shows that the lower the order of reaction, the earlier and more sharply it passes into the diffusional region.

An acetylene flame emits a continuous spectrum and band spectra corresponding with CH, OH and C_2. Avramenko[5], with a rarified acetylene-air flame, found a new band spectrum corresponding with the so-called 'ethylene bands' and supposed to be due to CHO. Changes of conditions led to its disappearance, so that CHO may be regarded as an unstable intermediate product in the combustion of acetylene.

Several papers on co-ordination compounds have appeared, for example, on hydroxylamine compounds of palladium[6], $[Pd4NH_2OH](OH)_2$ and salts, and very stable Magnus type compounds $[Pd4NH_2OH]\,[PtCl_4]$; thiosulphate compounds of palladium[7] of two types; and iridium sulphites of the type of Claus's salt[8].

Several interesting papers of metallurgical interest have been published[9].

In the field of organic chemistry, mention may be made of a synthesis of cyclopentylpentene[10], organometallic compounds of mercury[11], and the synthesis of olefins with a quaternary carbon atom[12].

It is not possible in such a short notice even to mention the many other interesting and important papers, but some indication has perhaps been given of the great activity in chemical research in the many institutions of the U.S.S.R.

FORTHCOMING EVENTS

Saturday, December 8

British Association for the Advancement of Science, Division for the Social and International Relations of Science (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1).—Conference on "Scientific Research and Industrial Planning" At 10.15 a.m.—"Economic Aspects of Research" (Speakers: Prof. P. Sargant Florence, Mr. F. E Smith, Prof M. L. E. Oliphant, F R.S); at 2.15 p.m.—"The Human Factor" (Speakers. Sir Arthur Fleming, Dr. C. P. Snow, Mr. J. Kendall, Prof. J. D Bernal, F R.S., Mr. J. A. Lauwerys).

North of England Institute of Mining and Mechanical Engineers (at Neville Hall, Newcastle-upon-Tyne 1), at 2.30 p m —Mr. F T. P. Dickins: "Training Within Industry".

Monday, December 10

Royal Geographical Society (at Kensington Gore, South Kensington, London, S.W.7), at 5.30 p m.—Major-General G. Cheetham: "New Medium and Small-Scale Maps of the Ordnance Survey".

Tuesday, December 11

Royal Society of Arts, Dominions and Colonies Section (at John Adam Street, Adelphi, London, W C.2), at 1 45 p.m.—Dr. E P Weeks: "Canada and Post-War Reconstruction".

Royal Institution (at 21 Albemarle Street, London, W 1), at 5.15 p.m —Sir Henry Dale, O M, Pres R.S . "Recent Developments in Chemical Therapeutics", (ii) "Sulphanilamide and its Derivatives"

Institution of Electrical Engineers, Radio Section (at Savoy Place, Victoria Embankment, London, W.C 2), at 5.30 p.m.—Discussion on "The Servicing of Radio and Television Receivers" (to be opened by Dr. R. C. G. Williams).

Royal Society of Medicine (at 1 Wimpole Street, London, W.1), at 5.30 p.m —Discussion on "D D.T." (to be opened by Prof. G. R. Cameron, Dr. A. Thelwall Jones and Dr H D. Clarke)

Illuminating Engineering Society (at the E.L.M.A. Lighting Service Bureau, 2 Savoy Hill, London, W C 2), at 6 p.m.—Dr. J. N. Aldington: "Bright Light Sources".

Society of Chemical Industry (joint meeting of the Nutrition Panel of the Food Group and the Institute of Brewing, at the Horseshoe Hotel, Tottenham Court Road, London, W 1), at 6 p.m.—Dr. F W. Norris: "Carbohydrate, Nitrogenous, Mineral and Alcohol Constituents of Beer"; Mr J W. Tullo · "Vitamins in Beer".

Quekett Microscopical Club (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 6.30 p.m —Scientific Papers.

British Institution of Radio Engineers, Scottish Section (at Heriot-Watt College, Chamber Street, Edinburgh 1), at 7 p m —Prof. M. G. Say: "Ultra-High Frequency Techniques".

Sheffield Metallurgical Association (at 198 West Street, Sheffield 1), at 7 p m.—Dr. C. Sykes, F.R S · "Hydrogen and its Importance in Large Masses of Steel".

Wednesday, December 12

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 1 45 p m.—Sir Horace Wilson, G C.B.: Amulree Memorial Lecture.

Institute of Petroleum (at 26 Portland Place, London, W.1), at 4.30 p.m —32nd Annual General Meeting; at 5.30 p.m.—Mr. J. F. Waters · "Some Problems encountered during Well Shooting Operations in the Nottinghamshire Oilfields".

Institution of Electrical Engineers, Transmission Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m. —Dr E. Billig: "Mechanical Stresses in Transformer Windings".

British Association of Chemists (joint meeting of the London Section with the Scientific Film Association, in the Cinema of the British Council, 3 Hanover Street, London, W.1), at 6.30 p.m.—Programme will include films on Penicillin, D.D.T., and the discovery of a new pigment.

Thursday, December 13

London Mathematical Society (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W.1), at 3 p.m.—Prof. G. F. J. Temple: "Newtonian Aerodynamics".

Royal College of Surgeons of England (at Lincoln's Inn Fields, London, W.C.2), at 5 p.m.—Prof. W. E. Le Gros Clark, F R.S.: "The Contribution of Anatomy to the War".

Royal Institution (at 21 Albemarle Street, London, W.1), at 5.15 p.m.—Sir James Jeans, O.M., F.R.S.: "Physical Astronomy", (iii) "The Dust and Gas of Interstellar Space".

Institution of Electrical Engineers, Installations Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m. —Mr. F. W. Tomlinson and Mr. H. M. Wright · "Mineral-Insulated Metal-Sheathed Conductors".

Society of Instrument Technology (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 6 p.m.—Mr. G. H. Farrington: "Automatic Temperature Control of Jacketed Pans".

Institute of Physics, London and Home Counties Branch (in the Reid-Knox Hall, British Institute of Radiology and Röntgen Society, 32 Welbeck Street, London, W.1), at 6.30 p.m.—Dr. E. G. Richardson: "The Production and Applications of Supersonics".

Women's Engineering Society, Manchester Branch (at the Engineers' Club, Albert Square, Manchester), at 6.30 p.m.—Prof. H. Wright Baker: "Recent Trends in the Education of Engineers".

Pharmaceutical Society (at 17 Bloomsbury Square, London, W.C.1), at 7 p.m.—Dr. C. J. Blok: "Pharmaceutical Conditions in Holland under the German Occupation".

Royal Society of Tropical Medicine and Hygiene (at Mans House, 26 Portland Place, London, W.1), at 8 p m.—Discussion "The Teaching of Tropical Medicine" (to be opened by Dr. L Evera Napier).

Friday, December 14

Physical Society, Optical Group (in the Lecture Theatre, Scien Museum, Exhibition Road, London, S.W.7), at 3.30 p.m.—Discussi on "The Coating of Optical Components to reduce Reflection" (to opened by Dr. K. M. Greenland).

Royal Astronomical Society (at Burlington House, Piccadill London, W.1), at 4.30 p.m.—Scientific Papers.

Royal Institution (at 21 Albemarle Street, London, W.1), 5.15 p m.—Prof. M. L. Oliphant, F.R.S.: "The Utilization of Nucle Energy".

Institution of Electrical Engineers, Measurements Secti (at Savoy Place, Victoria Embankment, London, W C.2), at 5.30 p. —Mr G. F. Shotter and Mr. H. D. Hawkes · "A Precision A.C /D. Comparator for Power and Voltage Measurement".

British Association of Chemists, St. Helens Section (at t Y.M.C A. Buildings, St. Helens), at 7.30 p.m —Mr. A. V. Harriso "Technical Education and its relationship with Industry".

Saturday, December 15

Association of Scientific Workers, Leeds Branch (at t Riley-Smith Hall, University Road, Leeds 2), at 2 30 p.m.—Seco Conference on "Science and Education". Prof. J. D. Bernal, F.R.S "The Policy of the Association of Scientific Workers in regard Science and Education".

Society of Chemical Industry (joint meeting of the Food Gro with the Yorkshire Section of the S.C.I. and the Hull Chemic and Engineering Society, in the Lecture Theatre of the Min Department, The University, Leeds), at 3 p m.—Mr. J. Pryce Jone "Honey".

APPOINTMENTS VACANT

Applications are invited for the following appointments on before the dates mentioned.

Engineering Assistant—The Engineer and Manager, Northampton Water Undertaking, Municipal Offices, Fish Street, Northampton (December 14).

Lecturer in Mechanical Engineering, to teach Productio Engineering Subjects, Machines Theory and Design—The Principa Derby Technical College, Normanton Road, Derby (December 14).

Assistant Engineer for large Rubber Works in Scotland—Th Ministry of Labour and National Service, Appointments Departmen Technical and Scientific Register, Room 670, York House, Kingsway London, W.C.2, quoting C.2806.XA (December 15).

Assistant Lecturer (temporary) in Mathematics—The Registra University College, Hull (December 15).

Lecturer (full-time) in Physiology—The Clerk to the Governin Body, Battersea Polytechnic, Battersea, London, S.W 11 (Decembe 15).

Secretary of the Appointments Board—The Registrar, Th University, Manchester (December 15).

Electrical Engineer by the Sudan Railways—The Ministry Labour and National Service, Appointments Department, Technica and Scientific Register, Room 670, York House, Kingsway, London W.C.2, quoting D.1590.A (December 17).

Civil Engineering Assistant—The Engineer-in-Chief, Sout Staffordshire Waterworks Co, 50 Sheepcote Street, Birmingham 1 (December 21)

District Mechanical Engineer (Workshops) by the Iraqi Stat Railways—The Ministry of Labour and National Service, Appointments Department, Technical and Scientific Register, Room 67 York House, Kingsway, London, W.C.2, quoting C.2429.A (Decembe 22).

Lecturer in Physics in the University of Cape Town—Th Ministry of Labour and National Service, Appointments Departmen Technical and Scientific Register, Room 670, York House, Kingsway London, W.C.2, quoting A.1197 A (December 29).

Assistant Lecturer in Botany—The Registrar, The University Sheffield (December 31).

Lecturer (full-time) in the Department of Physics and Mathematics—The Principal, Birmingham Central Technical College, Suffol Street, Birmingham 1 (December 31).

Lecturer in Physical Chemistry, and an Assistant Lecture in Chemistry—The Registrar, The University, Sheffield (Decembe 31).

Lecturer in Production Engineering at the Municipal College Southend on-Sea—The Chief Education Officer, Education Office Warrior Square, Southend-on-Sea.

Junior Assistant Bacteriologist (B Sc.) for Central Laborator —The Medical Officer of Health, 23 Montrose Street, Glasgow.

Research Assistant in the Department of Bacteriology—The Principal, Harper Adams Agricultural College, Newport, Shropshire.

Young Graduate, preferably in Physics or Physical Chemistry for research work on moulding materials, their properties and testing and a Young Graduate, preferably in Chemistry or Metallurgy for research on corrosion and related problems—The Director, Britis Cast Iron Research Association, Alvechurch, Birmingham.

Technical Assistants (Chemical) for Petroleum Research Laboratory in London area for small experimental plants—The Ministr of Labour and National Service, London Appointments Office, 1– Tavistock Square, London, W.C.1, quoting CN.48.

Bacteriologist with a good knowledge of serological method, t assist in the study of streptococci associated with acute disease i infants—The Secretary, National Institute for Research in Dairying Shinfield, Reading, Berks.

University [illegible] of Science
PHYSICS Dept.
Upper Circular Road

HIGHER TECHNOLOGICAL EDUCATION IN BRITAIN

THE need for a considerable expansion of the research effort of Great Britain is now generally accepted, and on every hand industrial concerns, industrial research associations, and government departments are taking steps to increase their research facilities. These efforts are being made on the assumption—and it must remain an assumption for some time to come—that there will become available more men and women capable of conducting research successfully. Granted this, however, those of our national problems which demand for their solution more scientific and technical research will in fact be solved only if there become available also more men and women capable of translating the results of research speedily and efficiently through the various stages of development into large-scale production.

It has not perhaps been sufficiently recognized that notwithstanding the paucity, in quantity, of the pre-war research effort of Great Britain relative to that of certain other countries, we did not compare unfavourably with any in the production of new ideas and the practical demonstration of new principles. Our deficiency lay in the ability to engineer our scientific and technical achievements on an adequate scale. Those who say that before doing more research we ought to use more effectively what has been done already are not speaking nonsense; they are giving warning of a danger which we shall be wise not to ignore in the years ahead.

The scope and difficulty of the whole problem of educating and training the technical personnel required by industry in these connexions has increased considerably with the rapid expansion and growing complexities of scientific knowledge and technical development. This problem has received much attention in Britain during recent years from the professional bodies concerned, and a report on the matter by a Committee appointed by the Government in April 1944 under the chairmanship of Lord Eustace Percy has been keenly awaited*. The terms of reference of this Committee were as follows : "Having regard to the requirements of industry, to consider the needs of higher technological education in England and Wales and the respective contributions to be made thereto by Universities and Technical Colleges, and to make recommendations, among other things, as to the means for maintaining appropriate collaboration between Universities and Technical Colleges in this field".

In its report, this Committee states that its original intention had been to make successive reports on the educational provision required to meet the needs of various industries, but that in view of the magnitude of the problem it has limited itself to a consideration of the field of engineering, and has used this to illustrate the form of organizing body which it recommends should be established. It has further limited its consideration to the 'professional' category of engineer. These restrictions are somewhat unfortunate, for much might have been gained from a comparison of the needs and experiences of the engineering and chemical industries, and also since the Institutions of Electrical and Mechanical Engineers have been laying stress on the rapidly growing importance of a grade of personnel lying between the professional and craft grades. This grade comprises men engaged as technical assistants in research and development, designer-draughtsmen, testers, inspectors, etc., for whom the technical colleges have thus far made little specific provision. The industrial demand for better trained men of these types is urgent, and the technical colleges have no more important function to discharge.

---

* Ministry of Education Higher Technological Education. Report of a Special Committee appointed in April 1944. Pp. 32. (London : H.M. Stationery Office, 1945.) 6*d*. net.

Hitherto, the main avenues to professional recognition in engineering in Britain have been degree courses at the universities and part-time national certificate courses at the technical colleges. The total pre-war output of these courses was about two thousand a year, of whom about one-third were university graduates in engineering and a small proportion holders of higher national diplomas gained by two years full-time attendance at a technical college. So late as 1937–38, four-fifths of the Higher National Certificate students received their instruction in evening classes, a system which is now generally recognized as wholly inappropriate to the standard demanded of the professional engineer.

During the War, the annual output of professionally qualified engineers has been raised to about 2,700, and the Committee estimates that this figure must be maintained. The present capacity of the university departments of engineering in Britain is stated to be about 1,200 a year, leaving some 1,500 to be accommodated by the technical colleges. The report divides the latter into three groups: 1,000, who will attain the Higher National Certificate via part-time courses, but on a day-time and not an evening basis; 150, who it is assumed will elect to work, as in the past, for a London external degree (although the system of external degrees is regarded by the Committee as an anomaly); and the remaining 350 for whom it is suggested specially planned courses should be provided.

Regarding these latter courses, the Committee states: "we would insist that such courses should be directed to the development of the highest level of the teaching of the art of technology, based on a sufficient scientific foundation. Such courses should have a status in no way inferior to the University type of course; they should require equal ability in the student; and they should afford a preparation for the most advanced post-graduate courses. But they will be different from University courses; and their development should not, therefore, be hindered or deflected by University affiliations or by arrangements for the grant of University degrees whether by existing universities—or, as some of our witnesses have suggested to us—by some new national technological university created purely for purposes of examination and standardization."

The provision of these special higher technological courses would be a function of a strictly limi number of technical colleges, to be called 'College Technology'. In addition, these colleges would expected to cater for a large volume of part-ti work leading to Higher National Certificates and I qualifications, and to develop postgraduate cour in special branches of technology "intended genera for their own graduates or for graduates from Univ sities, and for men who have been in industry some time". The colleges of technology would subject to the ultimate control of the providing lo authority in matters of finance and general polic but in order to ensure maximum co-ordination effort with adjacent universities and technical colle it is recommended that regional advisory counc and regional academic boards of technology be up, themselves co-ordinated in a 'National Coun of Technology'.

The need for a number of the larger technic colleges, acting in close collaboration with the univ sities, the professional institutions and local indust to provide both full- and part-time postgradua courses in the branches of technology relevant to th respective regions cannot be over-emphasized. Certa regional advisory councils for higher education a already engaged on this matter, and their effo would be strengthened considerably by the formati of a national co-ordinating body such as is suggeste With this aim of the recommendations there will general agreement; but there will be differences opinion on the case which the Committee has attem ted to make for the establishment of a new type undergraduate course, whatever be the title, B.Tec Diploma in Technology, associate of the Roy Colleges of Technology, by which, different groups the Committee suggest, success in the course mig be rewarded.

It is stated that failure to meet the demands of (t engineering) industry in the past have been d partly to deficiencies in the courses of education a training. Yet the Committee's analysis of these de ciencies does not extend beyond such tentative stat ments as "University undergraduate courses ma have been too short and too specialized", and " courses for the Ordinary and Higher Nation Certificates there may have been too little of th early scientific grounding which is as necessary to t art, as it is to the science, of engineering or of an other branch of technology". The Institution Electrical Engineers has not been so hesitant i its comments on the present inadequacy of t scientific foundation afforded by both these types course, and has asked that the deficiency be correct in both cases without delay. It can be corrected National Certificate courses, of course, only on th basis of a general replacement of evening by day-ti classes, and this arrangement the Percy Committ has in mind for the thousand engineers who are t attain professional status through this channel.

The Committee has not made clear enough how th new courses, intended to cater for 350 persons a yea are to differ from the improved versions of the ol which are to serve for the remaining 2,350 of the sam age-group. They are to emphasize the art of engi ring, "in which aspect it is concerned with the ecial application of general principles to particular oblems of production and utilization", but *not glect* the science, "in which aspect it is concerned ith general principles which are valid for every plication"; and they are to require equal ability to at required for success in a university degree course. iese are vague statements, and there are many hers. The suggestion of an undergraduate course ealing with the production side of engineering is not ow, but thus far no serious attempt has been made define a possible content or to assess the intellectual scipline which such a course would afford. These atters should have been dealt with more fully, and ust be clarified before a reliable assessment of the roposal can be made. The trend of informed opinion ould seem, however, to have been in the reverse rection.

The crux of the whole matter is that the production f the high-grade technologist requires a longer period ian we have been prepared to devote to it, and to vade this issue will be fatal. The complex problems ith which he is now faced demand that his training hall not merely *not neglect* science—by which should e understood the basic subjects of chemistry, physics nd mathematics—but shall aim increasingly at roadening his appreciation of it, and inspire the ealization that the impact of science on technology s a continuous and expanding process. Any action herefore which does not facilitate a tightening of the resent inadequate link between the two is retrogres-ive. For this reason the suggestion that colleges of echnology be set up separately from the universities nd their faculties of science requires the most careful onsideration. 'Colleges of Science and Technology' s an integral part of the university system appear more desirable goal, and would permit a more ready olution of the highly important problems of adjust-nent and of student transfer between universities and echnical colleges to which the report refers.

The scheme envisaged is superficially attractive; he advantages of full-time over part-time courses at the educational stage under consideration are unquestionable, while the administrative problems involved in implementing the recommendations would be minimal. This is no doubt an important consideration in times of emergency; but urgent as the problem may be, we shall be wise to consider before action is taken whether the courses and arrangements proposed are likely to produce the high-grade technologists required.

Other recommendations contained in the report are extremely welcome, and it is to be hoped that they will be acted upon without delay. Thus, in stressing the importance of a much increased flow of able boys from part-time to full-time courses of study, and referring to the manner in which this has been facilitated academically by the institution in some universities of an industrial matriculation, the Committee recommends an extension of the national system of scholarship awards to make this transfer more possible financially. It also recommends the institution of a campaign to increase the prestige and attractiveness of the technical professions; the establishment of a centre for the postgraduate study of industrial administration; and more positive arrangements to enable teachers of technology to keep abreast of industrial development. There is, of course, equal need for them to keep abreast of scientific development; and this, in itself, is a powerful reason for securing the closest possible merging of their departments with university departments of science.

INTERPRETATION OF FANTASY AS A CLINICAL TECHNIQUE

Controlled Projection (1944)

A Standard Experimental Procedure. Arranged by John C. Raven. Pp. 54. (London: H. K. Lewis and Co., Ltd., 1945.) 12*s*. 6*d*. net.

RECENT developments in projective technique offer a new approach to the mind, the exploration of which is just beginning. The underlying concept of projection (attributing our own 'qualities' to others) owes its origin to Freud. It was postulated to explain the origin of delusions of persecution and ideas of reference in paranoia. Freud thus identified a distinctive mental process of which we had only been vaguely aware. Many proverbs embody the belief that projection enters into daily intercourse. Folk-knowledge recognizes that in judging others we judge ourselves, that in condemning or condoning the actions of others we betray our own private inclinations. In the narrower sense in which Freud understood it, however, projection is a mechanism of defence employed, as an alternative to repression, with the aim of ridding the mind of an intolerable burden of aggression or guilt. Some recent experiments have thrown further light on these alternative *extra-* or *intro*-punitive processes.

Projection helps to shape our relationships with the outer world. We 'infer' from the dim or clear awareness of our own state of mind the state of mind of another person. It is not inference in the logical sense of inductive reasoning, but arguing by analogy from one particular to another. In Spearman's terminology, projection means educing correlates of our own social attitudes. Taken jointly, projection and correlate eduction are rich in explanatory value. Thus, to take one example, the late Prof. Aveling showed that ideas of cause and effect are generated (educed as correlates) by projecting on to external objects the experience of the self acting upon the organs and limbs of the body.

The recognition that projection plays a major part in the organization of mind has led to its being exploited as a method of penetrating beneath the surface of personality. Indeed, the importance of projective techniques to the psychologist has been likened to that of the X-ray apparatus to the physician. A person's projections can be evoked so as to uncover his innermost impulses, wishes, fears and values. He will interpret an ambiguous social situation in a way which, unknown to himself, will disclose some of the hidden secrets of his mind. In choosing his invective he will most likely dip into his personal inventory of self-condemnation. In forecasting an event on inadequate data he will project himself into his predictions, thus revealing what he *wants* to happen or what he privately fears *might* happen. He may perhaps project his own ignorance into the outside world. This last possibility was well exemplified by the Press in 1941 when ignorance of Japan's plans in regard to entering the War was projected on to the Japanese rulers, who were believed to be utterly uncertain of their own intentions.

Projective techniques are methods of indirectly locating crucial foci of value and conflict. Just as a searchlight, in projecting its beams on to an object, discloses its own location, so the mind by projecting its own wishes, hostility, fears and values, reveals its key centres of activity. Projection is something more than a subjective mental process. It has a social quality inasmuch as it is the main avenue for the mind's interpretation of its environment, human and material. Hence its significance for the study of interpersonal relations.

In England, projective techniques appear to have been first used by Wedeck in 1933 and described by him in a thesis deposited in the University of London library. His object was to inquire whether any 'group factor' existed which implied a special ability for understanding human character and relationships, whether, in other words, the interpretation of facial expression, gestures, social situations, proverbs and the like, required an ability statistically independent of general intelligence (Spearman's '*g*' factor). Wedeck did, in fact, claim to have detected a special ability of estimating character uncorrelated with '*g*'.

The potentialities of projective techniques in the study of personality were first fully appreciated, however, in the United States. H. A. Murray seems to have been early in the field. He set out the methods in his "Explorations in Personality", which attracted curiously little attention in England when it was published in 1937. He had a different purpose in mind; not to find out whether the subjects were good judges of character or not (as measured by some agreed criterion), but to discover their general mental and social orientation.

There is variety in projective techniques. The basic procedure requires that the subject should freely manipulate experimental materials presented to him. Alternatively he may be required to interpret the materials or situation, or he may be asked to carry out certain prescribed acts under observation. The underlying assumption is that the subject will employ the material or situation so as to express his inner values, his mental conflicts, his tendencies, aspirations and imaginary roles. He throws or projects himself into the medium of expression. Such techniques include the Rorschach Test, the Thematic Apperception Tests of Murray (briefly known as TAT), psychodramatic situations, and, in the case of children, play activities. Closely allied procedures are observations of expressive movement, posture, gait and physical activity of almost any kind. The fantasies projected by the subject or patient are not regarded as final indications of the trends in his mind but simply used as working hypotheses to be checked by other criteria. Murray's tests, which are the most important of these devices, were developed at the Harvard Psychological Clinic. In principle similar to the Rorschach Test, the material consists of reproductions of paintings instead of 'ink-blots'. The latest revision of the thematic apperception tests has just been published. Though originally devised for adults of normal intelligence, the tests have also been applied to mental defectives.

The exigencies of war soon determined that, in the interests of military efficiency, methods should be adopted for the assessment of personality in selecting personnel for higher duties. As is now perhaps well known, the important step was taken 1942 of introducing projective techniques into W Office Selection Board procedure as an aid in sele ing candidates on grounds of 'officer quality' or lead ship. Here the current tests of intellectual abilit were not appropriate and the new methods were great help in detecting weakness and strength in t personality structure of candidates, and in t adequacy of their social adjustment. Similar metho are now being employed in selecting candidates f the higher grades of the Civil Service.

Raven's work, stimulated by Murray's efforts a by the 'completion test' of a French investigat M. Thomas, introduces new steps in testing procedur part of which is common both to children and adults. The subject is asked to draw, and wh he is drawing, to imagine and describe a series events. Since he is occupied with two tasks there little residual energy left for self-observation or sel criticism. There are supplementary tests suitab for adults only. Although best results are obtain with individual administration, an adaptation of t test material is also provided for administration t adult groups.

Raven uses two kinds of material, verbal an spatial simultaneously, and he 'pursues' the subject fantasies in a number of prescribed directions. The is thus a twofold pursuit of the subject's projection In the result two distinct yet parallel forms of expression emerge side by side, one oral the othe pictorial; each is a check on the other. Both th verbal utterances and the drawings can be systematically followed, step by step, by the experimente until he is satisfied that his explorations of the subject's personality are as complete as necessary. Th materials used are simple and lack any structur of their own.

The ambitious aims of 'projection pursuit' ar clearly set out by Raven. It is not facts about th subject's past which are sought, but his interpretatio of the events of life, how he organizes his thought and actions, how he regards other people and how h imagines other people regard him, what motives h attributes to the actions of others, what are his like and dislikes, his wishes and judgments, and how, o the basis of these, his character is formed. Th sample records given by Raven illustrate (they ar not norms) what results are to be expected of childre at different age- and ability-levels within the norma range of intelligence. Some records are also given of th projections of adults differing in age, sex and ability.

Several criticisms of the present stage of Raven' techniques come to mind. The methods do not, as is claimed, appear to be appreciably subject t controlled variation. Nor do the results lend themselves at all easily to statistical treatment. Above all, to interpret the records is exceedingly difficult, and practically no guidance is offered on the subject. Raven admits that much has still to be learnt about the most informative questions to be put, about the best methods of pursuit, and about ways of recording the responses. These limitations the reader will readily concede.

The value of the present arrangement of test material lies less in what it achieves than in what it foreshadows. It provides not so much a procedure ready for clinical application as a "method of enquiry suitable for experimental work"; it is therefore as a pioneer effort that the work is to be judged, and the reader must not be too critical, though there is much to criticize.

JOHN COHEN.

OIL EROSION IN NEW ZEALAND

il Erosion in New Zealand
Geographic Reconnaissance. By Kenneth B. umberland. Pp. xi+227+43 plates. (Wellington: il Conservation and Rivers Control Council, 1944.)

A FIVE-YEARS survey convinced the author "that New Zealand, the youngest of the British ominions, has a soil-erosion problem of greater nificance in its relation to the future well-being the country than has any one of the older members the Commonwealth". He estimates that more an two thirds of the occupied area suffers from an-induced erosion.

The author approaches his subject from the geo-aphical rather than from the agricultural point of ew. Erosion in New Zealand has a regional char-ter, assuming distinct forms according to the imate, geology and related land use. Four erosion gions are distinguished in the North Island and ur in the South Island. The most striking, and in e North Island one of the most prevalent, forms erosion is the landslip which has devastated mense areas following the clearing of the bush. andslip erosion is the consequence not, only of uman intervention, but also of the geological struc-ure of the country. It seems to occur as a result a slight disturbance in a delicately balanced quilibrium of physical and biological forces—most equently on steep, deforested land that has gone own to grass. A secondary result of erosion that as caused widespread damage in New Zealand has een the silting-up of rivers and consequent floods. somewhat unusual form of erosion that is prevalent certain areas is called by the author "subcutaneous rosion", and results in the washing away of the npermeable subsoil while the permeable, grassed opsoil remains intact. Ultimately gullies and sink-oles are formed. The rapidity with which erosion as occurred in New Zealand is due in no small easure to the extensive and repeated use of fire s a means of clearing the virgin bush.

Since New Zealand possesses few other major atural resources besides the fertility of the soil the roblem of control is urgent. The author is more oncerned with erosion than soil conservation, though he latter is discussed on general lines, and regional chemes based on adapting land use to the limitations mposed by the natural environment are suggested. lthough the separate measures recommended—fforestation, improvement and control of pasture and, contour cultivation and strip-cropping—are hose which are commonly advocated elsewhere, they equire a different and unique synthesis into an ntegrated land-use programme, for the New Zealand limate is, on the whole, more maritime and less ubject to extremes of temperature and humidity han the climates of most countries where erosion ontrol has been scientifically studied. The author tresses the need for intensive research and State ction on a large scale. In 1941 the Soil Conservation nd Rivers Control Act became law, and a Soil onservation and Rivers Control Council was set up ith wide powers to carry out both conservation neasures and research.

Sufficiently detailed accounts are given in a series f appendixes of the geological, climatic, vegetational nd soil characteristics of the country to enable the eader who is unacquainted with New Zealand to et a clear picture of the geographical background of the problem. The book is illustrated with numerous beautiful and dramatic photographs. It should be read by everyone who is interested in this grave and widespread disease of the land. G. V. Jacks.

THE ELEMENTS RAGE

The Elements Rage
By Frank W. Lane. Pp. xii+188+47 plates. (London: *Country Life*, Ltd., 1945.) 10*s*. 6*d*. net.

THE more violent manifestations of Nature are of relatively infrequent occurrence, and so come into one individual's experience only at long intervals. If, then, we had to rely on the experience of one man only we should have a very inadequate picture of these abnormal phenomena. The author of the book under review has read and summarized a very great mass of literature dealing with hurricanes, tornadoes, waterspouts, hail, snow, lightning, meteorites, earthquakes and volcanoes, and from this has produced a readable book, in which a chapter is devoted to each of the nine topics enumerated above. To describe the book as readable is not to say that the reader will wish to devour it in one sitting. The rather overwhelming phenomena described can only be regarded as suitable for absorption in fairly small doses.

With the view of keeping the book free from error, so far as possible, the author had each chapter read over by at least one expert in the subject dealt with. The result has been to produce what is, on the whole, a reasonably accurate description of the phenomena, with an acceptable theoretical discussion in such parts of the book as call for theory. Here and there we find slips, which appear to indicate errors on the part of the experts, or failure of the author to listen to his experts. Thus on p. 2 we find the statement that "meteorologists define wind speed as the velocity with which the wind would carry a very light object, such as a fragment of thistledown, in a perfectly open situation, thirty-three feet above the ground". This is inaccurate, since wind speed can be defined at any height above the ground, and the wind at 33 ft. (10 metres) is a convenient specification of the surface wind.

But apart from a few unimportant slips, the treatment of the subject is clear and simple, and the book is well illustrated with photographs of tornadoes, waterspouts, hailstones, meteorite craters, earthquakes, volcanic eruptions, and of some of the dreadful damage produced by these phenomena. Among the most interesting parts of the book must be reckoned the four pages that describe the new volcano Paricutin in Mexico, which appeared in February 1943, the first new volcano to appear on the American continent in nearly two centuries. Paricutin appears to outdo Vesuvius in violence, being distinguished by its habit of spouting a hail of large fragments of lava thousands of feet into the air, and so endangering all forms of life in its immediate neighbourhood. A photograph of Paricutin in eruption appears as the frontispiece to the book, showing the magnificent plumes of smoke which tower high above the summit.

Mr. Lane has performed a very useful service to all who are interested in the violent manifestations of Nature, by writing a coherent account of these, and collecting into one volume the known facts relating to them. The book deserves to be widely read. D. Brunt.

DUBLIN COLLOQUIUM, 1945

By Prof. MAX BORN, F.R.S.
Department of Mathematical Physics, University of Edinburgh

THIS year's Colloquium or Summer School of the Dublin Institute for Advanced Studies was held during July 5–18. I have described the character of the Institute and of these annual meetings in a review of Schroedinger's lectures on "Statistical Thermodynamics"[1]. The lecturers of this course were Dirac (Cambridge), Jánossy (Manchester) and myself, to whom was added less officially W. H. Peng, my former Chinese collaborator, who has now been appointed assistant professor at the Dublin Institute.

The audience was more international than during the war-time colloquia; apart from Peng, there were students from Brazil, Ceylon and Palestine, an Austrian sent by a London body (British Electrical and Allied Industries Research Association) and others. Yet the majority was Irish, some of them priests of the Roman Church. Coming straight from the Academy celebrations in Moscow, I was struck by the profound contrast between these two scientific meetings: there the materialistic idea that science has to serve social progress by producing practical results, here a spiritual attitude of pure research without regard to applications. The character of the conferences corresponded to these fundamental attitudes: in the U.S.S.R., stimulating addresses on wide topics by scholars of all nations, to vast audiences, and visits to enormous laboratories; in Eire, a small number of experts assembled for intensive study and discussion of a few abstract problems.

Yet, great as the difference of atmosphere may have been, one thing there was in common: the acknowledgment of the importance of fundamental research and of the perfect freedom of thought in its pursuit.

In fact, the experience in the U.S.S.R. and in Eire have strengthened my conviction that these two aspects, which are the driving forces behind scientific activity in Governments as well as individuals, are not contradictory but complementary, in a similar sense as the wave and corpuscle aspect are in quantum physics. Practically, both attitudes lead to a result pleasant to the man of science, namely, a highly honoured position in the community. The reception which we members of the Dublin Colloquium were given by the Government, the National University and Trinity College was no less friendly and in its smaller frame no less splendid than that I had experienced in the U.S.S.R.

The lectures and discussions covered three subjects: cosmic rays, quantized field theories and quantum mechanics of crystals.

Jánossy's six lectures dealt with our present knowledge of cosmic radiation, which consists at least of three different components: (1) a soft component (electrons and photons); (2) a hard component (mesons); (3) a component which is primary with respect to the (short-living) mesons, consisting probably of neutrons and protons. Jánossy's report was mainly concerned with the third component, which is much less thoroughly studied than the other two; only one of his lectures was devoted to a feature of the soft component—the cascade theory of showers of photons and electrons. His account of this very complicated mathematical theory was an astonishing fe considering it came from a man we used to look up as an experimentalist. Concerning the third compone Jánossy reported first on observations made Rossi and Regener[2] of a non-ionizing component high altitudes, and then on his own work, in coll boration with Rochester[3], near sea-level. This no ionizing radiation is extremely weak and can observed only with the help of particular tric The apparatus, consisting in a vertical coinciden arrangement of counters, has to be shielded again undesirable ionizing particles. Since absorbers wou obviously not do, the shielding was performed wi the help of a box full of counters (76 in numbe in 'anti-coincidence' arrangement. Only tho discharges of the inner counters are registered 'anti-coincidences' which are not accompanied by discharge of any of the screening counters in th box. An ionizing particle coming from outside th box must necessarily discharge at least one of th screening counters before reaching the inner arrang ment; it produces, therefore, no 'anti-coincidence But a non-ionizing particle entering the box fro outside does not affect the screening counters; b a proper arrangement of scatterers inside the bo it has the opportunity of producing an ionizin secondary which is then registered. In this way th existence of non-ionizing rays more penetrating tha photons could be established.

Showers of penetrating particles have been observe by Wathaghin and his co-workers[4] and indepen dently by Jánossy[5] with the help of various counte arrangements. The rate of these penetrating shower was found to increase when absorbers of lead wer placed above the counters; this indicates the pro duction of secondary penetrating showers in the lead The particles responsible for these showers wer shown to be partly ionizing and partly not; the mean range was found to be about 5 cm. of lead All these experimental results can be interpreted i terms of the theory, developed by Hamilton, Heitle and Peng[6], of the production of mesons by nucleon

Another set of observations is concerned with th spreading-out over large areas of penetrating shower consisting of many particles[7]. The total energy o such showers is extremely high, and no interpretatio of this phenomenon has been given so far.

Dirac's main subject was quantum electrodynamic (four lectures). But one additional lecture wa devoted to quaternions, as a particular homage t their discoverer, Dublin's greatest mathematician Sir William Hamilton. In this lecture, Dirac deal with the application of quaternions to Lorentz transformations.

Previous work on this subject has always connecte the Lorentz transformation with bi-quaternions, bu here the need for introducing bi-quaternions wa avoided by subjecting ordinary quaternions to group of linear transformations with a denominator which group is then reduced to just the Lorentz group. The method leads to an elegant formulation of the law of addition of velocities in relativity theory in terms of quaternions.

Dirac's method of treating quantum electrodynamics is to keep closely to classical electrodynamics The Lorentz equations of motion of charged particle (including radiation damping) together with Maxwell' field equations may be considered as an exact classica scheme, which can be put into Hamiltonian form by using the 'Wentzel field'. From this Hamiltonian form of classical electrodynamics one can pass ove the quantum theory by the same rules as for rticle mechanics. The difficulty that then arises to solve the resulting wave equations, as the linary perturbation method leads to divergent egrals.

One can make some progress by the device of troducing redundant field variables. This makes e solution of the wave equations much easier and oids the divergent integrals, but throws the fficulty on to the question of interpretation. If e keeps to the standard method of interpreting ve functions in quantum theory, one must eliminate e redundant variables, and this would again troduce the divergent integrals if one expresses the ave-function as a power series in the electronic arge. However, from the general form of the wave nction in the redundant variables it seems likely at one can carry out the elimination by better athematical methods not involving power series, ithout getting divergent integrals. If this is so, it ould mean that the appearance of divergent in-grals in the solution of the wave equations is to be tributed to wrong mathematical methods and not any fault in the physical theory.

A further lecture dealt with the way the wave nctions of quantum electrodynamics transform under orentz transformations. These wave functions are not xpressible in terms of tensors and spinors in space-ime, but involve a new kind of quantity with an finite number of components, which has already een dealt with[8].

Finally, a lecture dealt with what one can say bout the *position* of a photon. A particle in non-elativistic quantum theory can have its position pproximately defined, and its state is then described y a wave packet. This is no longer possible in elativistic theory; but it turns out that there is omething playing the part of a wave packet, de-cribable mathematically in terms of a complex ariable of position

My own lectures consisted of two quite different ets. In the first set (two lectures) I dealt also with uantum electrodynamics, or more generally with uantized field theories. The infinities appearing in hese theories may be either a consequence of wrong hysical assumptions or of bad mathematics. In he first case one must try to find a weak point in he present theory, this seems to me the use of the rdinary Fourier transformation connecting space o-ordinates with momentum components. Peng and I have shown that one can replace the Fourier method by a new set of commutation laws for the field components; the elementary oscillators repre-sented in the older theory by quantized Fourier coefficients appear now as irreducible parts of the set of matrices representing the field components. To these parts we have given the name of 'apeirons'. The distribution of the apeirons can be chosen in such a way that the infinite integrals of the older theory become convergent. I further stressed the point that a satisfactory theory of interaction between different kinds of particles can only be achieved by treating all of them on the same footing, as quanta attached to the corresponding fields.

From this point of view Peng has made a careful investigation of the mathematical methods used in deducing the properties of particles, or quantized fields, in interaction; he gave a short account of this work in two lectures.

The ordinary method consists in an expansion with respect to powers of the coupling parameter (electric charge in the case of photon-electron inter-action); this method fails because the unperturbed system is highly degenerate. Just as in ordinary quantum mechanics one has to apply the method of secular perturbations, Peng has shown how this can be done for a quasi-continuous spectrum. His results confirm in first approximation the theory of radiation-damping given by Heitler[9] and Wilson[10]. It seems certain that Peng's method allows us to calculate higher approximations for radiation and collision cross-sections without divergent integrals About the question of self-energy, however, there was a controversy; Peng believed he had obtained a finite value of the so-called 'transversal self-energy', but Dirac raised objections to the proof. (Peng has since informed me that he has confirmed his state-ment.) The ordinary 'longitudinal' self-energy is not covered by Peng's present results; this infinity appears also in the classical theory and I doubt if it can be avoided in quantum mechanics except by Dirac's λ-limiting process.

My last three lectures were devoted to a much simpler subject, some problems of the theory of crystals. Raman and his collaborators have attacked ordinary lattice dynamics on account of optical experiments and tried to replace it by another theory. The main difference is this: they contend that a crystal lattice has only a finite number of vibrations, I think 48n, where n is the number of particles in the cell, while the straightforward appli-cation of dynamics (classical or quantum theory) leads, of course, to the result that the number of vibrations is $3Nn$, where N is an extremely large number, namely, that of the cells. It would not be worth while to refute Raman's theory if all known facts could be explained by lattice dynamics; but that seems to be not the case. The reason is that the theory was developed before the discovery of quantum mechanics; the semi-classical model of a lattice used in my book[11] is insufficient. It is not the dynam-ical part, the theory of vibrations, that is deficient, but the optical part. The deformability of the ions had not properly been taken into account, but this can be easily done by describing their structure with the help of wave functions. I have revised the whole theory of crystals from this point of view and obtained a great number of new results. An example is the theory of pyro-electricity. There was an old discre-pancy between experiment (Ackermann[12]) and theory (Boguslawski[13], Born[14]) with respect to the temper-ature dependence near the absolute zero; it was experimentally found to be proportional to T^2 while the theory gave T^4. This is now cleared up; the improved theory leads also to T^2. A second example is the fine structure of the residual rays (Reststrahlen) found by Barnes[15] and others. Blackman and I[16] have tried to explain it by taking into account the anharmonicity of the lattice vibrations. But I now consider this idea to be wrong; the phenomenon is a direct consequence of the deformability of the ions. Closely connected with this is the Raman effect of the second order. The first successful experiments were made by Fermi and Rasetti[17] on rocksalt; they interpreted their results in the correct way as a continuous spectrum with a number of small narrow maxima. Krishnan[18], however, claims these maxima to be a line spectrum as predicted by Raman's theory. Dr. Mary Bradburn and I[19] have developed the theory in detail and shown that the continuous background and the maxima as well can be derived in fair agreement with the experiments. I do not doubt that the improved lattice theory will be able to explain all cases of Raman effect and other phenomena observed by the Indian physicists.

THE ROYAL SCHOOL OF MINES

GEOLOGY, MINING AND METALLURGY AT THE IMPERIAL COLLEGE

By Prof. W. R. JONES

TOWARDS the middle of the last century, at the dawn of the industrial age, when the demand for machinery to quicken the pace of life was becoming more and more insistent, the value of the application of scientific knowledge to the many problems confronting Great Britain and the British Empire was becoming realized slowly but surely. In no sphere of activity was the need for such knowledge more marked than in increasing the supply of metals. The pressing demand for these necessitated the search by geologists for the minerals containing the metals; the working of the mineral deposits required mining engineers; and the extraction of the useful metals needed metallurgists. If rapid progress were to be made, it became manifest that the training of geologists, mining engineers and metallurgists was a matter of profound importance. It was the insistent demand for such training—not then available anywhere in the British Empire—that gave birth to what later became known as the Royal School of Mines.

At this period the Geological Survey had as its head Sir Henry de la Beche, a man of outstanding personality and vision who not only dominated the Survey but also wielded great influence with the Government. He had accumulated a large collection of minerals, geological maps, plans of mines and drawings of mining machinery which he housed at Craig's Court, adjoining Scotland Yard, London. This was opened to the public in 1841 as a Museum of Economic Geology to "exhibit the practical application of geology to the useful purposes of life". The exhibit aroused such great interest that the need for more accommodation caused the Government to erect a new building, and on May 12, 1851, the Museum of Practical Geology in Jermyn Street was opened by the Prince Consort.

This gave de la Beche the opportunity he had long cherished of using the Museum and its collection for training in mining and applied science; and months later, on November 6, he delivered t inaugural address as director of the Governme School of Mines and Science applied to the Arts. preparation for this new School, he had gather around him a group of the most eminent men in the particular subjects: Warington W. Smyth f mining and mineralogy; Andrew C. Ramsay f geology and its practical application; John Perc the 'father of English metallurgy'; Robert Hunt f mechanical science with its application to mining. Edward Forbes for natural history applied to geolog and the arts; and Lyon Playfair—afterwards Lo Playfair—for chemistry applied to the arts an agriculture. It is an outstanding tribute to the geni of de la Beche in the selection of his staff that eve member of this brilliant group became a fellow of th Royal Society and achieved international fame; an together they established for the School an unsu passed reputation throughout the Empire.

After the death of Sir Henry de la Beche in 185 Sir Roderick Impey Murchison, a virile leader, succeeded after many rebuffs in changing the title of th School in 1857 to the Government School of Mines and in 1863 to the Royal School of Mines, the titl which it still retains as one of the components of th Imperial College of Science and Technology. Th School was transferred in 1872 from Jermyn Stree to the Royal College of Science (now the Huxley Building) in South Kensington, and, in 1913, to it nearby present home in Prince Consort Road.

The Royal School of Mines is essentially a teachin institution, fulfilling the purpose for which th Imperial College of Science and Technology was incorporated: "to give the highest specialised instruction, and to provide the fullest equipment for the most advanced training and research in variou branches of science, especially in its application to industry". Its particular function is training in the application of the principles of science and engineering to the fundamental industries of mining, metallurgy, and oil.

Geology

From the initial stages of the School, the Geology Department has been closely linked with the Mining and Metallurgy Departments, and with the passage of time this link has become more strongly forged, for now the three departments are housed together in the Royal School of Mines. Two thirds of the students of the Department receive the associateship of the School; the remaining third, studying pure geology, belong to the Royal College of Science. During the last twenty years almost all the students attending the School in any of its departments sit also for the Honours B.Sc. of the University of London.

Sir Henry de la Beche, the founder of the School, Sir Roderick Murchison, his successor as its director and head of the Geological Survey, and Sir Andrew Ramsay, its first professor of geology (1856–76), were all eminent geologists, who played a great part in laying the sure foundations of their science and in building upon them its broad developments. Their achievements have become incorporated in the body of the science.

Advances in geology are rarely spectacular; it is more a case of "precept upon precept, line upon line, here a little, and there a little". The Geology Department can look back with satisfaction on a century of productive research in all branches of the subject.

dd (1878–1905), who succeeded Ramsay, made nd contributions to the Jurassic and Cretaceous atigraphy of Great Britain, and the results of his vestigations into the complexities of the Tertiary lcanicity of the Hebrides are of signal merit. It s been truly stated of him that he established the rst thorough course of practical instruction in ology established in Britain, and perhaps in the rld". He trained a group of practical geologists o have made their mark on geological science in parts of the world—a group containing Boulton, enville Cole, Hume, Sir Thomas Holland, Skeats, llis, Tyrrell, Morley Davies, Rutley, Sherlock and any others is no mean memorial.

Judd was followed by W. W. Watts, who occupied e chair during 1905–30. His contributions to the atigraphy and petrology of Shropshire and the idlands remain of fundamental importance to the ology of Britain. Invaluable also have been his rvices to the science as its counsellor. Building on the foundations of his predecessors, he expanded e departmental courses to keep abreast of progress, d in his teaching he inspired his students and lleagues to undertake research work in various anches of geology. Under his guidance, two new b-departments were instituted to supply men ained for special work in the oil and mining indus- ies. That in oil technology, comprising geology, rveying and engineering was established in 1912; nd under the direction of Prof. V. C. Illing it has ospered exceedingly and has supplied fully trained en to oil companies in various parts of the world. he second special training is in mining geology, hich includes in addition to geology, surveying, ssaying and the principles and economics of mining. his training was fostered by Prof. C. G. Cullis with uch success that the demand for graduates in mining eology has always been greater than the supply. ullis was followed in the chair by W. R. Jones, its resent occupant.

Under Watts there thus began the production of ighly trained practical geologists, many of whom ow hold chairs in British universities, are members f the Geological Survey, directors of Colonial eological Surveys or consultants to mining and oil ompanies. A roll of the distinguished old students nd colleagues of Watts would include Boswell, racewell, Brammall, Bulman, Dewhurst, Eastwood, roughton Edge, Fitch, Hitchin, Holmes, Ingham, ones, Lepper, Read, Edmondson Spencer, Stubble- eld, Wade, Wayland, Whitehead, Whittard and any more.

In this way, the Geology Department of the Royal chool of Mines, like those of Mining and Metallurgy, as made a very great contribution to Colonial and mperial development, and can justly consider itself worthy part of an Imperial College. While a most mportant function of the Department is this training f high-class geological technicians for the oil and ining industries, just as important a function is the rovision of postgraduate training, especially for ominion, Colonial, Indian and foreign graduates. n many occasions, the student population of the ostgraduate school of the Geology Department has een made up of men from a dozen countries.

Watts was succeeded by Prof. P. G. H. Boswell, ho continued the development of the postgraduate hool and himself established much of the basis of odern sedimentary petrology following his important ork on British glass- and moulding-sands. In 1939, oswell retired for health reasons and was followed by the present head of the Geology Department, Prof. H. H. Read. The codification of views upon granitization and its relation to metamorphism have been the subject of three presidential addresses by Read, and his far-reaching proposals for a genetic classification of rocks are widely acknowledged to merit careful consideration.

Among researches carried out in the Department during the last decade may be mentioned those of Illing on oil geology, Hobson on the compaction of sediments and the properties of clay suspensions, Wood on the algæ, Jones, Brammall and Leech on the etiology of industrial dust diseases, Brammall and Leech on metamorphic granitization as developed in Dartmoor and the Malverns, and many more.

The chief contributions to the advance of geology during the last century from the Geology Department have thus been the establishment of the basic principles, a large output of competent original work, a great production of trained men especially in oil and mining geology fitted for service abroad, and the formation of a strong and varied postgraduate school which attracts students from all parts of the British Empire and from foreign countries.

Mining

The progress during the century in underground activities is no less important, though less known, than that of surface transport from the days of the stage-coach to the most modern motor-car. Especially is this so in the type of mining with which the Royal School of Mines is concerned. Hand-drilling has been replaced by pneumatic-drilling, gunpowder by gelignite and other highly efficient and safer explosives, hand-loading by mechanical scrapers; transport from the working-face of the broken ground is no longer by man-power but by mechanical traction, horse-whins for raising the material to the surface have given place to power winding-machinery, pits of a maximum depth of a few hundred feet have become shafts thousands of feet in depth, and ventilation arrangements of the crudest kind have been replaced by well-planned systems employing large fans of high efficiency, aided, in the deepest and hottest mines—some of which are more than a mile and a half below the surface—by refrigerating plants. These are some, but not all, of the great improvements in the art of mining during the last few decades.

Concerning all these advances, the Mining Department of the School has been and still is the premier place in the British Empire for the training of the mining engineers who, in co-operation with other engineers in their different spheres, have made such progress possible.

The Department was particularly fortunate in its first professor, Sir Warington Smyth. On leaving Cambridge, Smyth spent four years on the mining fields of Europe and the Near East, advising mining companies and collecting representative samples of minerals and rocks from those fields. On his return, he joined the staff of the Geological Survey, became chief mineral inspector of the Office of Works and of the Duchy of Cornwall and adviser to the Crown on all mining matters. His knowledge of geology, and of its practical application to mining, formed the basis on which he built the mining course at the School. Since his day the subjects forming the course have increased considerably in scope with the progress of science; but during the hundred years that have elapsed, the principles of geology have remained a fundamental part of the training of the mining engineer.

Smyth was followed in the chair by Clement le Neve Foster, Herbert Cox, William Frecheville and S. J. Truscott, all men of great eminence in the mining industry before they accepted the professorship. They were able to present to their students first-hand information concerning the mining problems of their day and the improvements they visualized in the future, thus to inspire their hearers to keep abreast of their subject and to retain the international reputation of their forerunners. The standard of athletic prowess set by the first head of the Mining Department—a Rowing Blue—has been maintained by the present head, Prof. J. A. S. Ritson, a former English International Rugby player.

Progress in mining is achieved in the mines, not in college laboratories. Some practical improvement in the art of mining is of almost daily occurrence; and although this is the fruit of research, it is not of the kind that results in the publishing of scientific papers. Thus it is that the strength of the Department lies in its training to bring about these useful practical improvements in the mines rather than in research work carried out within its doors.

In fulfilling this, its most important function, it has been very successful. The excellence of its training has attracted students from all parts of the British Empire. The Department is unique in the number of awards granted to its past students by professional mining institutions, and in the positions of highest responsibility in the mining world occupied by its *alumni*. The A.R.S.M., the diploma awarded to its students, has an unsurpassed reputation in the Dominions and the Colonies, where almost all its students go on leaving the School; and the demand by the Colonial Governments and mining companies for those trained in the Department has always been greater than the supply. Particularly is this so during the past few years, when only a small fraction of the posts offered could be fulfilled.

Metallurgy

The first English text-book on metallurgy was written by Dr. John Percy, the first professor of metallurgy at the Government School of Mines and of Science applied to the Arts, later to be known as the Royal School of Mines. Percy has been truly described as the 'father of English metallurgy', and it could well be stated that for the first decade of his professorship, his department was the cradle in which British metallurgy was nurtured. Among the results of his many successful researches was the adoption for the Patera process in 1858 using sodium thiosulphate for the leaching of silver ores.

In those early days, phosphoric iron deposits remained useless as a source of iron, for no method was known by which the deleterious phosphorus could be removed. Percy Carlyle Gilchrist, in association with his cousin Sidney Gilchrist Thomas, and inspired by John Percy, carried out experiments which ultimately established the basic Bessemer process for converting phosphoric pig iron into good-grade steel. The first patent was taken out in 1877 and from it was developed the modern basic steel industry.

Percy was professor during 1851–80, and was followed by Sir William Chandler Roberts-Austen (1880–1902), an exceptionally able and inspiring teacher, who fostered the growth of physical metallurgy—then in its babyhood—to such a degree that his team of researchers, which included D. G. Bengough, O. F. Hudson, W. H. Merrett and Stansfield, made notable advances in the study metallography.

William Gowland, then a well-known authority the metallurgy of copper, followed Roberts-Aust and was professor during 1902–9. He completed t Fifth Alloys Research report, the first four havi been published by his predecessor.

For the five following years, 1909–13, the ch was occupied by William A. Carlyle, who had be manager of Rio Tinto Mines and smelter. His wi experience in industry enabled him to impress on h students the importance of understanding practic operations on a large scale.

Sir Henry Cort Harold Carpenter was profess from 1913 until his tragic death in 1940. Under h direction, considerable advances were made in t study of corrosion of metals and, in collaborati with Miss Elam (Mrs. Tipper), the first single crysta of aluminium were produced, thereby providing da which have proved of fundamental importance. chairman of a large number of Government cor missions and research institutions, he was able exercise great influence in promoting the advanc ment of knowledge in a wide variety of metallurgic operations.

In the course of the century, the Department h produced many metallurgists of outstanding eminenc and professors who, in their turn, have grafted o their universities the courses initiated at their *Alm Mater*. Among its brilliant students were C. Bannister, C. V. Boys, A. J. Brett, A. C. Claude Sir Lewis Fermor, P. C. Gilchrist, F. W. Harbor O. F. Hudson, W. F. Hume, Henry Louis, A. McCanc B. McNeill, T. A. Rickard, E. Riley, Sir Thoma Rose, S. W. Smith, A. Stansfield, T. Turner, an E. A. Wraight.

The Royal School of Mines, proud of its achieve ments, is beginning its second century in a spirit high endeavour, fully confident that it will continu to produce the highly trained geologists, minin engineers and metallurgists who during peace an war have served Britain and the British Empire wit conspicuous success.

THE ALLIED PLAN FOR EDUCATION

By Dr. E. F. ARMSTRONG, F.R.S.

THE United Nations Educational, Scientific an Cultural Organisation (U.N.E.S.C.O.) commence its deliberations in London on November 1 and wa able to have its constitution agreed and signed by the representatives of forty-four nations on November 16. The principal object of this Conference wa to draw up the constitution of the new body; th delegates attended primarily, therefore, in a diplomatic rather than an educational capacity.

Perhaps the outstanding achievement to many o us is the inclusion of the word 'Scientific' in the titl as well as in all pertinent places in the text. Scienc has now world recognition as an equal partner i the great task of world educational reconstruction

It is generally recognized that the failure to se up an educational body on the same lines as th International Labour Office after the First Worl War was a serious omission. The remarks of th ime Minister, Mr. Attlee, at the first session of) Conference, form the first sentence of the preible to the constitution "that since wars begin in ə minds of men, it is in the minds of men that ə defences of peace must be constructed". It is education alone that men of all classes in all untries can get to know and understand one anher. Hence the general view among delegates that ey were forging the best possible instrument of ace—a peace based on the intellectual and moral idarity of mankind.

The first and most immediate object of N.E.S.C.O., when it begins its real work, must to bring help to education in the backward untries. A backward citizen is not necessarily a d citizen, but his country will be stronger in the easure that he ceases to be illiterate.

People are thinking to-day as perhaps never before. ere is universal agreement on a higher standard of e for all, though silence about the fact that it reires education both to attain it and enjoy it. Some vocate a classless society without realizing the possibility of there being any such thing. The ascist State, whether of the extreme right or the treme left, advocates the vice of mass thinking; ientific workers lead in demanding freedom of ery kind. Pessimists proclaim that nothing will er be the same again, while the optimists hope change human nature by 'order in council'. The uth is that we are unable to decide between what permanent and what is ephemeral, or as Charles organ has so admirably said, "the middle truth pears to be that in all societies and at all times ere are both constants and variables, and that hat gives to an age its distinguishing character the relationship, the friction between them".

But this article is primarily to deal with the effect the new organization on science, national and ternational. It can be profound, but the future ust be shaped by our own efforts; it cannot and ust not be left to others while we sit back and iticize.

The U.N.E.S.C.O. originated, as is well known, in art from the Conference of Allied Ministers which egan work in London on the initiative of Mr. R. A. utler, then Minister of Education, in October 1942. July 1943 it set up a Science Commission. The rimary work of the Allied Ministers Conference was make preparations so as to be ready to aid the ssential work of educational and moral reconstruction hen their countries were freed; hence the original sk given to the Science Commission was to work ut the requirements for scientific and laboratory quipment. A general picture of the problem as a hole was obtained and, for the first time, an idea the magnitude of the scientific equipment of the ountries concerned was gained. As a result of their ork seventy-six detailed inventories—of many housands of items—have been compiled. These rm a unique catalogue of the necessary equipment f laboratories for a wide range of sciences such as ad never before existed. They will form valuable orks of reference for many years to come and greatly cilitate both the task of rehabilitation and the etting up of a laboratory in any part of the world.

Apart from this specific achievement, the Science ommission has taken all possible steps in a variety f directions to be able to guide and assist the restoraon of science at all levels in the occupied countries, nd it can form a basis for the science division of the reparatory Commission of U.N.E.S.C.O.

Perhaps it is appropriate here to chronicle that the Conference set up a Preparatory Commission to take all necessary steps to bring the new body into physical being and start its work, in particular to get ready the agenda for the first real meeting, which can only take place after a sufficient number of nations have ratified their acceptance of the constitution. When this happens the home of U.N.E.S.C.O. will be Paris. In the meantime Sir Alfred Zimmern is acting as secretary and the business is being conducted from London.

Two different themes were in the minds of all the delegates: one, the legalistic drafting of the constitution; the other, humanitarian, the need to help in rehabilitation of the devastated countries. It required skilled conduct on the part of the chairman of the various meetings to keep the two subjects separate in the discussions. Finally, the rehabilitation aspect was referred to a Technical Committee to be set up by the Preparatory Commission and to come into being at once.

The last session of the Conference was devoted to restoration and closed on a high note of urgent need; the meetings which followed immediately concerned themselves with procedure and oratory and involuntarily brought to mind those words of Macaulay:

"Those behind cried forward,
Those before cried back."

Admittedly, it is difficult to see how best to ensure the provision of aid since this is dependent inevitably upon action by individual nations or existing international relief organizations.

The Conference had before it as the working document a White Paper prepared by the Allied Ministers Conference which substantially was adopted. In this White Paper the word 'Science' was lacking, but its insertion was urged by the United Kingdom delegation largely on the insistence of Miss Ellen Wilkinson, who so efficiently acted as president of the Conference. The proposal met with no serious opposition. Arguments as to whether science is included in 'Culture' are interminable and serve no useful purpose. The nations of the world were concerned, not Britain alone, and to them the inclusion of the specific word 'Science' had a real meaning.

Delegates from the South American countries, from Turkey, China, Egypt and many other, including the Arab countries, all gave the assurance that new status had been given to teachers of science so that their powers would be increased and their prestige enhanced. The same consequence can be made to apply even in Great Britain, where science is still largely an extra, though honourably bracketed with music and dancing!

Charles Morgan writes of "a confluence of ideas flowing from the nations into the stream of civilization". The opportunity now exists to make science supply some of the tributaries of this stream!

Nature, in its issue of November 15, gave full space to the views expressed by some of our leaders regarding the proper future organization of international science, so that there is no point in expressing further views of a detailed character.

The constitution of U.N.E.S.C.O. is permissive, as every well-drafted instrument should be. 'May', for example, in Article 8, enables it to co-operate with outside international bodies presumably of repute, whereas 'shall' is mandatory and forces recognition of any body with headed stationery and a brass plate on the door.

The primary and indeed essential need is for science to be represented from the very beginning on the Secretariat of U.N.E.S.C.O. The secondary action may well be for us, first nationally and then internationally, to make the existing or new scientific organizations of various types both representative and efficient so that they can claim recognition from U.N.E.S.C.O. at an early stage. The proposals put forward by the Association of Scientific Workers, as representing the work which the scientific division of U.N.E.S.C.O. should do, are admirable but they would take several years to bring to fruition, and demand a large and highly qualified administrative staff at a moment when there is a great dearth of scientific workers for productive work. Moreover, the question arises whether all these matters should be handed over to bureaucrats, for that is what they will become, even though they started as men of science. The docile are not always the virtuous. Is it not wiser to maintain the freedom which we cherish, which some think we are in danger of losing, and organize these things for ourselves while becoming closely affiliated to the world organization ?

There is so much to do to-day that we are accustomed to priorities in every sphere of activity. U.N.E.S.C.O. must have priorities, some undoubtedly far higher than the claims of advanced science : this is the main reason why we must do some things for ourselves if they are to be done soon.

Happenings the world over rightly interpreted may be taken as evidence of strength in our civilization. The responsibility for the recreation of the moral life of the world will fall heavily on us; in this we dare not fail. As R. A. Butler wrote the other day, the Conference "must ensure that the world of Education, like that of Science, does not become the plaything of purely Governmental machinery, either in any one country or in any international organisation".

In the next few months U.N.E.S.C.O. will have to establish its organization. It has a precedent in the International Labour Office. The Executive Board is representative of eighteen governments and elected by the Conference ; there is to be a director-general and a permanent secretariat. Perhaps it should at once break down its work into sections, of which science will undoubtedly be one. Men of science should proceed without delay to set out in clear and, above all, practical terms, avoiding too great a length, the work and problems which this Science Section should envisage as its first tasks. It must be remembered that the non-scientific workers have still to be educated regarding the nature and the value of the help which the scientific attitude of mind can give them ; at present they are sceptical, even suspicious of the motives of men of science and confused by the scientific habit of speaking with so many contrary voices on any subject.

The Conference was well attended, several countries sending large and influential delegations. As always on these occasions, perhaps most was effected by private conversations or smaller meetings, among which were several for the scientific delegates.

Many delegates were closely connected as teachers with education in their own countries, including some of the more backward in the educational sense. They were outspoken in the benefits which U.N.E.S.C.O. could give them : money spent on education instead of armies, a life in which cultural interests, the drama, art, science and literature could play a part instead of power politics and the fear of future war; a life in which mutual understanding and knowle instead of ignorance of each other's ways and li could be developed; a life of travel and intercha of visits (extending over weeks and months) children, students, teachers, professors, resea workers, all men and women of sympathy and go will promoting peace and an international outl instead of narrow nationalism and suspicion; a in which technical progress was for the service man and not for his destruction.

INSTITUTION OF METALLURGIST

INAUGURAL MEETING

AS a craft, the metallurgical art is of the great antiquity : in the speculative development natural science, the metals have played an importa part. During the Middle Ages, the Guilds and Live Companies exercised a beneficial influence in manding proofs of competence from the craftsm working with metals; but as the importance of th bodies decreased, this control diminished, and sin then, until the last few weeks, there was no organi tion, in Great Britain at least, which was responsil for certifying metallurgists as being professiona competent. University qualifications are clear pro of this ; but there are many who, for reasons outsi their own control, have never had the opportuni of obtaining such training or 'hall-mark'.

In the Iron and Steel Institute and the Institu of Metals, Britain possesses two bodies which ha done great service to the metallurgical industrie and to the community in general, as the avenu through which metallurgical research and develo ments have been made known ; but membership neither is recognized as proof of more than intere in the ferrous or non-ferrous metals.

For some years, there has been a growing feelir that a strictly professional body, somewhat simil to those which exist for chemists and engineers, w needed, and the two Institutes have had the matt under consideration. It was ultimately decide that the demand would be best met by th establishment of a new organization, admitting onl qualified workers in the field of metallurgy, an having functions supplementary to, and independen of, the two existing metallurgical institutes.

On September 15, 1945, the new Institution Metallurgists was incorporated and licensed by th Board of Trade, and on November 28 the inaugura meeting was held, under the presidency of Dr. H Moore, at 4 Grosvenor Gardens, London, S.W.1, th offices of all three bodies. Attended by metallurgists of repute in all branches of the art and science— the presence of Prof. T. Turner, the *doyen* of Englis academic metallurgists, gave, perhaps, the greates pleasure—and with the support of representatives o very many similar scientific and professional societie the support and collaboration of which will b most welcome, the Institution was launched unde conditions of the most complete harmony.

After outlining the reasons for the formation o still another society, Dr. Moore expressed his and th Institution's satisfaction at the presence of so many distinguished guests, and pointed out that th Institution was still under the control of a 'caretake government' until the first general election of officer to be held in the earlier part of next year. He the introduced the Hon. R. G. Lyttelton, treasure tho Iron and Steel Institute, who on behalf of one he 'parents' wished the Institution every success.

W. T. Griffiths, president of the Institute of tals, followed and reminded the meeting of the k done by the late Dr. T. Swindon in the early s of the discussions which had that day come fruition. Throughout, the assistance of the two ent organizations was most cordially acknowledged. The value of the work of Dr. Moore himself, and that of Mr. K. Headlam-Morley, the secretary of both Institutes and of the new Institution, was stressed by Dr. J. W. Jenkin, vice-president, without which the formation of the Institution would have been considerably delayed.

To these gentlemen and to the two Institutes, the Institution of Metallurgists owes a very deep debt.

NEWS and VIEWS

ence and Reconstruction

In addressing the Manchester Joint Research uncil on "Science and Reconstruction" on Decem- 6, Sir John Anderson referred to his own early eer to emphasize that a good grounding in natural ence can be a passport to the higher Civil Service l that public administration does provide scope, art from the professional or specialist grades, for n with a scientific training. Sir John associated nself with the view that the restoration of the nomic life of Britain, and even the maintenance pre-war standards of living, depends on building our industries to a level of efficiency higher than er before attained; and in support of this view referred to some outstanding British technical hievements during the War to establish his contion that, while we have lagged behind in the past d men of science have to get rid of prejudice ainst applied science, the prognosis for the application of science in industry during the period of reconuction is extremely favourable. Considering what still needed, Sir John dealt first with the question personnel. The output of scientific workers is low that which the real needs of the country mand, and too little was made of the importance scientific and technical education during the ssage of the Education Bill last year; indeed, the eds of industry may at first have to give way to ose of the universities. Urging the importance of eparing a quantitative and qualitative estimate of ture requirements of trained men and women, Sir hn welcomed the appointment by the Lord President of the Council of a committee to deal with the estion of scientific man-power and also pressed accelerating the release from the Forces of trained en of science and students.

Dealing next with the question of finance and the cent increased Government grant to the universities Britain and to the new allowances in regard to x relief for research expenditure, Sir John instanced number of recent university endowments by dustry as illustrating the value of such relief. He lieves that so far as financial aid is concerned, we ve a framework within which all that is required n be secured. The efficient use of the limited sources of Britain, however, demands the best ssible organization, and here Sir John suggested worthy of exploration a number of questions in gard to remuneration, mobility and interchange of aff and information or ideas, pensions schemes and e like on the lines of the recommendations in the cent Barlow Report on scientific staff. Research applied science in teaching institutions should not discouraged, though they should not be encouraged undertake agency or contract work. The adntage of allowing some fundamental research in dustrial research establishments should be recognized, and industrial associations might discuss with representatives of the universities and Government research organizations long-term programmes of research and what fundamental researches can most profitably be conducted in Government establishments or centrally in selected institutions.

Sir John Anderson unhesitatingly rejected the idea of a Minister of Science and suggested that the Lord President of the Council should be formally recognized as the Minister responsible for dealing, on behalf of the Cabinet, with all general scientific questions in which the Government is concerned, including problems of organization and arrangements for Commonwealth or international conferences. The Scientific Advisory Committee should be placed on a peace-time footing with some extension of staff, as the principal adviser of the Lord President and the Cabinet in scientific matters. Sir John would also create a special section of the Cabinet secretariat to assist the Lord President in the discharge of his new responsibilities. Finally, referring to the investigations into atomic energy, Sir John said that nothing had been discovered to justify the expectation that the energy released by an atomic explosion could be used directly as a source of industrial power. The only practicable method appeared to depend on the conversion into heat of the energy released by a controlled process of nuclear fission. The vast range of new radioactive substances, including radioactive forms of common elements used in medicine, which the new devices provide is probably much more important and beneficial and may bring a revolution in medical science.

Industrial Research in Great Britain

The Industrial Research Bill introduced into the House of Lords on November 29 by Lord Barnby was withdrawn after a speech by Lord Pakenham in which he indicated that although there was no active opposition to the principle of an enabling Bill, only about a dozen industries out of the eighty or ninety consulted by the Government on their post-war problems had indicated that they might take advantage of such legislation to finance any of the joint activities mentioned. Owing to the extreme pressure on parliamentary time during the present session, the Government would be unable to give facilities for the Bill; but whatever might be the position in the future, finance is not at present the main trouble. After referring to the announcement of the Lord President of the Council in his speech on November 6, Lord Pakenham emphasized that the Government appreciates that in some industries a statutory levy would give research associations the security of revenue necessary to allow them to plan useful long-term research and would have other advantages. Accordingly, the Government had the matter still much in mind, along with the allied question of statutory levies to finance other desirable co-operative activities. The Government does not wish to discourage industries which have plans under consideration from proceeding to work them out in detail, even if those plans will ultimately need statutory power to give effect to them. Emphasizing the importance which the Government attaches to a rapid improvement in the scientific basis of our industrial production, Lord Pakenham said that the Government could do a little to help in that matter; but primarily such improvement must depend on the willingness of industrialists themselves to devote resources to research, and it must depend still more on their willingness to exploit the results of scientific research.

Dr. A. D. Imms, F.R.S.

Dr. A. D. Imms has retired from the readership in entomology at Cambridge, which he had held with distinction since 1931. Dr. Imms was the first holder of this readership, the establishment of which resulted from an endowment by the Rockefeller Foundation, made with the avowed intent of strengthening in Great Britain those sciences which are fundamental for agriculture. The appointment of Dr. Imms seemed almost inevitable. After taking his degree in London, Dr. Imms held an 1851 Research Scholarship at Corpus Christi College, Cambridge, during 1905–7, and then took up the appointment of professor of biology in the University of Allahabad; for two years, during 1911–13, he was forest zoologist to the Government of India, after which he became reader in agricultural entomology at Manchester, establishing there a tradition for entomological research which has lived on. But it was not until his transfer to Rothamsted in 1918 as chief entomologist that his full stature came to be appreciated. In 1924 Dr. Imms published his "Text-book of Entomology", and at once he became recognized as the leader of entomology in Great Britain. This excellent book has gone through three editions, and is almost as widely used in the United States as it is in Britain. "Recent Advances in Entomology" followed in 1931, and during the War Dr. Imms produced an admirable "Introduction to Entomology". The influence of these books has been immense, and will long continue. It is good to know that Dr. Imms intends to pursue his literary work in the milder climate of Devon, and we may hope that the entomological world at large may long enjoy what Cambridge has regretfully lost.

Dr. V. B. Wigglesworth, F.R.S.

Dr. V. B. Wigglesworth has been appointed to the readership in entomology in the Department of Zoology, Cambridge, vacated by Dr. A. D. Imms. In addition, he is in charge of a Unit of Insect Physiology of the Agricultural Research Council. After some postgraduate work in biochemistry at Cambridge, Wigglesworth held posts in the Department of Entomology at the London School of Hygiene and Tropical Medicine, during 1921–43. The Department was under P. A. Buxton, who was interested in precise field-work on the ecology of insects, and Wigglesworth made complementary studies on physiology, exploring many sides of the subject, including the behaviour of insects. His work went deeply into the pure science, the view being taken that a proper understanding of physiology is one of the foundations of applied entomology. He shov himself a master of the carefully planned experim and of the simple technique. Not infrequently experiments with insects have proved to be importa contributions to general physiology. His book, "T Principles of Insect Physiology", first published 1939, is an important contribution to biologi science.

Dr. Kenneth Mellanby

Dr. Kenneth Mellanby has been appointed the University readership in entomology tena at the London School of Hygiene and Tropi Medicine in succession to Dr. Wigglesworth from October 1. During 1930–36 Dr. Mellan was engaged in research work at the London Sch of Hygiene and Tropical Medicine, and in 19 he was elected Sorby research fellow of the Ro Society. He joined the R.A.M.C. in 1943, but w released in 1944 in order to proceed to South-E Asia for research on behalf of the Medical Resear Council.

Earthquake in the Arabian Sea

The greatest shock ever recorded by the Rivervi Observatory, Australia, was registered by seism graphs throughout the world about 10.6 p.m. G.M on November 27. The epicentre may have been ne lat. 24° N., long. 64·5° E., about 180 miles fro Karachi in the Arabian Sea. *The Times* corresponde at Delhi suggests it may have been near the doul ridge which encloses an 8,000-ft. deep gully on t bed of the Arabian Sea. The ridge was first plott by the John Murray Expedition of 1933–34 and probably a continuation of the Kirthars Range b tween Sind and Baluchistan. Mr. E. W. Pollard, the Isle of Wight, recorded the earthquake 22h. 06m. 24s. G.M.T.

At Karachi the shock was accompanied by rumbli but no damage has been reported except for a fe broken windows. The earthquake was felt througho the Las Bela State of Baluchistan, and at Banjiguar Baluchistan. A tremendous sea wave, presumab caused by the earthquake, occurred about the sar time at several places on the coast. In the Bomb suburbs of Juhu and Versova boats were smash at their moorings and some people standing on t shore were carried out to sea. The bodies of thr women were recovered. It is reported in *The Tim* that the bodies of seven of the nine persons caug by the wave at Mahalaxmi, opposite Bombay's rac course, have been recovered. Most of the victi appear to have been caught on the causeway co necting an ancient Muslim mosque, which is bu on a rocky outcrop, with the mainland. This caus way is usually under water at high tide. The wa was most severe on the coast of Makran, north-we of Karachi. At Pasni a number of people are r ported to have been washed away and the post a telegraph office together with other buildin damaged. The Government of India has vot one lakh of rupees for the relief of victims. The da age and loss of life, though great, is thought at t moment to have been estimated too high, and offic figures are awaited. The officer in command of t Royal Indian Navy warship *Hindustan*, the fi relief ship to reach the coastal area in question, h signalled news of two new islands in the Arabian S about 180 miles west of Karachi. They are stat to have appeared after the recent earthquake a be three miles apart. One has an area of about one square mile and the other one and a half square miles.

In the past, a great earthquake occurred in the tate of Cutch on June 16, 1819. This earthquake aused damage over a vast area and extensive changes in level in the crust of the earth. In Bhuj early 7,000 houses were overthrown and 1,140 bodies aken from the ruins. Half the town of Anjar was also destroyed with large loss of life. More recently, earthquakes have also occurred in Baluchistan in 919 and 1931 (*Nature*, April 27, 1935, p. 661). It ppears fortunate that the recent earthquake occurred eneath the sea some miles from land, as otherwise, with a shock so tremendous, without doubt there would have been enormous damage to property and oss of life.

A Biological Council

MANY biologists have felt for some time past that he activities of the specialized societies to which hey belong remain largely unknown to other biologists who happen to belong to different societies or associations, although often the activities of these other societies are of direct interest to them. The officers of various biological societies have frequently felt the need for more information about the arrangements made by their fellows so as to avoid unnecessary clashes of dates of meetings or duplication of discussions on subjects that might advantageously form the basis of a joint meeting. In an endeavour to provide some common meeting ground for the representatives of the various biological societies, the Committee of the Biochemical Society in the autumn of 1944 called an informal meeting of representatives of a few societies which it was thought might be interested in the proposal. In all, three meetings, attended by representatives of fourteen biological societies, were held afterwards in the rooms of the Royal Society.

It was finally decided that a Biological Council should be formed consisting of the representatives of the various societies which were sympathetic to the scheme. The first meeting of this Council, at which Sir Henry Dale took the chair, was held recently in the Linnean Society's rooms. Dr. W. P. K. Findlay, of the Forest Products Laboratory, Princes Risborough, Dr. W. T. J. Morgan, of the Lister Institute of Preventive Medicine, London, and Prof. J. Z. Young, University College, London, were elected secretaries. While the immediate objects of the Council will probably be limited to such matters as the dates and subjects of the general meetings of societies, it is envisaged that the scope of the Council's work may enlarge and that many editorial and other problems relating to the societies' publications may fruitfully be discussed in common.

Plant Pathology in Palestine

ON the occasion of his seventieth birthday in November 1944, Prof. Chaim Weizmann was presented with a volume of researches by members of the Division of Plant Pathology of the Agricultural Research Station, Rehovoth, Palestine. This volume, describing researches carried out under war conditions, testifies to the zeal and energy of the phytopathological staff of the Station. The subjects dealt with cover a wide range, and include diseases of lettuce, beans, cucumbers, tomato, potatoes, citrus, cereals, clover, apple and pear scab, and fungicides. All the papers have since appeared in the *Palestine Journal of Botany*, but the collection brought together is a worthy tribute to a great leader. The remarkable progress in agriculture effected by the Jews in Palestine has no doubt been greatly fostered by the help and assistance afforded by the work of the Agricultural Research Station at Rehovoth. Of the many interesting items mention may be made of four only: a rare parasite of potatoes is constituted by powdery mildew, due to an unidentified species of *Oidium*, which first became epidemic in 1941, and again in 1942 and 1943; the occurrence of the apple and pear scab in all parts of Palestine but on local varieties only, as the European varieties are some weeks later in growth and regularly escape infection; the novel and ingenious suggestion of using the overhead system of irrigation, now largely in vogue in Palestine, for the application of fungicides; and the occurrence of *Ustilago nigra* on barley, the first record of this species of smut outside North America, and of immediate practical importance as this pathogen is susceptible to seed disinfectants.

British Radio Industry

THE fundamental scientific principles of radiolocation and the startling results obtained from its application during the War have now become common knowledge. While the conception of this important new weapon is a tribute to British scientific research, and its success in practice demonstrates the ability of the Fighting Services to utilize a highly technical development, there is a necessary intermediate factor, which must not be forgotten, in the form of the design and production facilities available during the time of the country's direst need. The Radio Industry Council has dealt with this last aspect of the subject in a booklet recently issued under the title "The British Radio Industry in War and Peace" (Radio Industry Council, 59 Russell Square, London, W.C.1). The object of this small publication is to tell the world what British men of science, engineers and workpeople have accomplished in the past five years in the application of the whole field of radio technique to war-time requirements, and the manner in which the experience gained during this terrific effort will be applied to the post-war development of broadcasting and television receiver production.

The British radio industry, which in 1935 produced nearly two million broadcasting receivers for ordinary listeners, was the main source of supply of the technical personnel required by the Services during the War to instal, operate and maintain radiolocation and communication equipment. In spite of this loss of some of its most valuable workers, the radio industry was called upon to supply, at high pressure, tremendous quantities of equipment and components of all types. A typical and impressive example of the scale of the radio equipment required is given by the fact that in any one of our thousand bomber raids many thousands of valves, cathode ray tubes and other electronic devices were in the air with those machines; while at the same time there were further very substantial quantities of all kinds of co-operating equipment in use on the ground. The Radio Industry Council has developed largely from the industry's war-time growth, and it is actively engaged in co-ordinating and furthering the interests of the whole radio manufacturing industry through the four independently constituted associations which deal respectively with the manufacture of valves, components, complete equipments and with general radio communications and electronic engineering.

An Abstracting Service for Human Biology

THE trustees of *Biological Abstracts* announce the establishment, beginning in January 1946, of a new section—Section H, specially assembled Abstracts of Human Biology—intended for anthropologists, sociologists, psychologists, neurologists and psychiatrists, students of child development and human welfare, and students of man generally. The new section will be an assemblage of all abstracts published in *Biological Abstracts* dealing with the broad field of human and social biology. Biological studies on human inheritance, population and fertility, endocrine and neurological factors affecting growth, development and human personality, alcoholism and drug addiction, and nervous disorders and mental deficiencies, and broad nutritional and epidemiological studies affecting human welfare, are some of the many fields that will be covered. Further information may be obtained from Mr. H. I. Anderson, Biological Abstracts, University of Pennsylvania, Philadelphia 4, Pennsylvania.

Survival of a Fish after a Major Injury

A POPULAR article by Elizabeth C. Pope in *The Australian Museum Magazine* (8, No. 11, 383) records the survival of a specimen of *Meuschenia skottowei* after the loss (at some previous date in its existence) of three fifths of the tail end of its body. The fish was swimming in the customary position when it was caught in Port Jackson. A photograph of the specimen shows an interesting modification of what, originally, must have been mere remnants of the dorsal and ventral fins. These appear to have grown backwards and round the severed end of the body in order, apparently, to compensate for the loss of the tail as a propelling organ. Dissection showed that the back had been severed clean between vertebræ, and in such a position that little more than the head remained. Most of the gut, though intact, was found to be displaced, and, though the internal organs were crowded, the swim-bladder appeared normal. At least two of the major blood-vessels must have been severed at the time of the accident; but death by hæmorrhage was evidently prevented by crushed tissue sealing the cut ends.

University of London Appointments

DR. KARL MANNHEIM has been appointed to the University chair of education tenable at the Institute of Education as from October 1, 1945. Since 1933 he has been lecturer in sociology at the London School of Economics and since 1941 he has been attached to the staff of the Institute of Education.

Dr. Walter Freudenthal has been appointed to the University readership in dermatological histology tenable at University College Hospital Medical School as from October 1, 1945. Since 1934 he has been research worker and assistant to the Dermatological Department of the School.

The title of professor emeritus in morbid anatomy in the University has been conferred on Prof. G. W. de P. Nicholson, who was University professor of morbid anatomy at Guy's Hospital Medical School during 1922–44.

Dr. D. M. Newitt, reader in chemical technology at the Imperial College of Science and Technology since 1937, and since 1941 director of scientific research of the Inter-Services Research Bureau, has been appointed to the Courtaulds chair of chemical engineering tenable at the College as from October 1.

Dr. Alan Moncrieff, of the Middlesex Hospital an the Hospital for Sick Children, has been appointe to the Nuffield chair of child health tenable at th Institute of Child Health as from January 1, 194

Royal Geographical Society Christmas Lectures

THE two Christmas lectures of the Roya Geographical Society will explain in non-technica terms the evolution of survey and map-productio methods down to the advances achieved during th War. On December 31, Major C. A. Hart will spea on "Modern Maps and how they are Made", and o January 4, Dr. Edward Lynam, in charge of the Ma Room of the British Museum, will deal with som "Early Map Makers", and early methods of surveyin from the time of the fourteenth century. The lectur will be supplemented by an exhibition which wil be open during December 31–January 5 in th Society's House, Kensington Gore, London, S.W.7

Physical Society's Exhibition

THE thirtieth Exhibition of Scientific Instrument and Apparatus, arranged by the Physical Society will be held at the Imperial College of Science an Technology, Imperial Institute Road, South Kensington, S.W.7, on January 1 (2.30 p.m.–9 p.m.), January 2 (4 p.m.–9 p.m.) and January 3 (2.30 p.m.–9 p.m.). The leading manufacturers of scientific instrument will be exhibiting their latest products in the Trade Section. The Research and Educational Section wil contain contributions from research laboratories, and experiments of educational interest. Discourses will be delivered on January 1 at 5.30 and 8.15 p.m., on "The Optical Industry in the War", by Captain T. Martin; on January 2, at 5.30 and 8.15 p.m., on "Radar", by Sir Edward Appleton; on January 3, at 5.30 and 9 p.m., on "Modern Plastics and Cements", by Dr. J. C. Swallow. Admission to the Exhibition is by ticket only. Members of institutions and scientific societies may obtain tickets from their secretaries; tickets may also be obtained direct from the Exhibition Secretary, 1 Lowther Gardens, Exhibition Road, S.W.7.

Announcements

PROF. ARTTURI VIRTANEN, of the Biochemical Institute, Helsinki, has been awarded the Nobel Prize for Chemistry for 1945.

THE managers of the Royal Institution have appointed Prof. Eric K. Rideal, professor of colloid science in the University of Cambridge, to be Fullerian professor of chemistry in the Royal Institution and director of the Davy Faraday Research Laboratory, in succession to Sir Henry Dale, who retires from both posts on September 30, 1946.

PROF. H. A. KREBS has received a message from Dr. T. Bucher, who worked with Prof. Otto Warburg, stating that Prof. Warburg is alive and well. Apparently Prof. Warburg went to his country house on the Island of Rügen in January 1945, and returned to Berlin in June.

THE foundation members of the newly formed Medical Academy of Sciences of the U.S.S.R. met recently to vote for the first elected members and corresponding members of the Academy. Among those elected to membership were A. E. Braunstein, N. R. Rogansky, R. R. Timofeevsky, P. K. Anochin, D. N. Nasonov and N. F. Gamalea.

A Simplified Chemical Notation

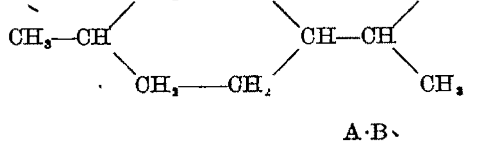
Some twenty years ago and more I suggested an abbreviated notation to a few chemical friends, who old me that the old method was all they needed, and was too well established to be disturbed. But he thing has recurred to my mind, and I am encouraged to think there may be something in it after all.

Suppose a tetrahedral molecule, with C in the middle, and four H-atoms, not at the apices, but on he *facets* of the tetrahedron; and let us call it A. Lay one such molecule on another; two facets (or two H-atoms) are thereby obliterated. A was CH_4, A_2 is now C_2H_6, and A_n is the whole series of the paraffins. It is obvious, and at the root of the matter, that A, which began as CH_4, may signify CH_3, CH_2, or even C, according to its place in a arger molecule.

Suppose another tetrahedron, on one face of which he H-atom is replaced by —OH, and call it B; his is methyl alcohol, AB is ethyl alcohol, and A_nB is the series of monohydric alcohols. The isomers of these explain themselves; for propyl alcohol (A_2B) may be AAB or ABA, and so on. The primary alcohols are A_nB, the secondaries are A_nA_mB, and the tertiaries are $A_nA_mA_pB$. The polyhydric alcohols have the general formula B_n; glycol is B_2, glycerol s B_3, and so on.

A third tetrahedron (D) has two of the four H-atoms replaced by O; it is formaldehyde, and A_nD s its homologous series. Acetone is formaldehyde to which two methyl groups are added on; its formula is ADA, and that of the higher ketones is A_nDA_m. Formic acid (CHOH : O) becomes a fourth tetrahedron, E; acetic acid is AE, and A_nE is the series of the fatty acids.

To include the nitrogen compounds we use a letter *N*) for the ammonia radical; methylamine is A*N*, dimethylamine A_2N, and so on; but we must distinguish ethylamine, AA*N*, from A_2N. It will be useful to have a single letter (K) for the benzene ring; but we may deal otherwise with the cyclic compounds. For as A_n represents a linear, or successive, series of methane groups, so let some such symbol as $\{A_n\}$ represent the same in cyclic form. $\{A_6\}$ will represent the single-bonded cyclic C_6H_{12}; and, by a further convention, $\{\{A_6\}\}$ may represent the double-bonded cyclic C_6H_6, that is, the benzene ring itself. As an example of a cyclic formula, take menthol (the alcohol):



This we may now write as $A\cdot A\genfrac{}{}{0pt}{}{A\cdot B}{A\cdot A}A\cdot A_3$, or as $A\{A_5B\}A_3$. But enough of examples.

Life-time of the Neutral Meson

The circumstance that neutral mesons have thus far escaped all attempts at experimental detection can, if one assumes these particles to exist at all, be accounted for by ascribing to them a very short lifetime, τ_n, where τ_n refers to the rest system of the neutral meson. In fact, τ_n should be smaller by several orders of magnitude than the corresponding quantity for charged mesons, τ_{ch}.

It has been pointed out by Sakata and Tanikawa[1] that a neutral meson can decay into p photons, $p \geq 3$, a process which gives the desired connexion $\tau_n \ll \tau_{ch}$: for $p = 3$ they find $\tau_n \sim 10^{-16}$ sec. $\sim 10^{-10}\tau_{ch}$. However, the reasoning of these authors would not seem to be conclusive as it involves, contrary to other life-time calculations, the cutting off of a divergent integral, namely, that of the momenta of the protons occupying negative energy-levels. Thus so long as the mystery of the divergences in quantum field theory has not been solved, the above numerical result remains questionable. Therefore, it may be of some interest to inquire whether there is another way of accounting for the short life-time of neutral mesons which does not involve cut-off integrals.

Clearly such a possibility exists: we have merely to assume, first, that in close analogy to the decay of charged mesons, the neutral meson disintegrates according to (the notation will be obvious)

$$Y^0 \rightarrow e^+ + e^- \text{ , } Y^0 \rightarrow n + n' \text{ ; } \quad . \quad . \quad . \quad (1)$$

secondly, that

$$\frac{g_{ch}^2}{\hbar c} \ll \frac{g_n^2}{\hbar c}, \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

where g_{ch} (g_n) denotes the strength of the coupling of charged (neutral) mesons with the electron-neutrino field.

In the customary treatments, one puts instead of (2)

$$\frac{g_{ch}^2}{\hbar c} = \frac{g_n^2}{\hbar c} \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

(which, together with (1), would yield $\tau_n = \tau_{ch}$). The only reason for using (3) is analogy. In fact, relations similar to (3) for couplings of mesons with nucleons are employed in symmetrical theories of nuclear forces, where they find their experimental justification in the charge independence of nuclear forces. But has this analogy any physical background?

The fact that there exists a coupling between the various meson fields and the electron-neutrino field means that there are forces between electron-neutrinos, of the exchange (ordinary) type due to charged (neutral) mesons which can, to a first approximation, be computed by the second-order perturbation formula

$$\sum_i \frac{H_{Ai}\,H_{iF}}{E_A - E_i}.$$

In the nucleon case, the same formula can be used. But whereas it is there possible (to a first approximation with respect to v/c) to neglect the dependence of $E_A - E_i$ on the energy of the nucleons (neglect of recoil), this is impossible in the case of the electron-neutrino because the quanta (virtually) created by the electron-neutrino are heavy compared with the particles by which they are created: the electron-neutrino forces are from the outset relativistic.

This means: (1) there is a dissymmetry between electron-electron and neutrino-neutrino forces on account of the different rest masses entering into the energy denominator in both cases; (2) comparing a charged with a corresponding neutral interaction of the same strength, that is, using equation 3, it is readily seen that, for similar reasons, another dissymmetry exists, namely, between 'like particle' and 'unlike particle' forces. Therefore we may state that, even if equation 3 holds true, there is in the electron-neutrino case no equivalent of the charge independence of the interaction between nucleons as brought about by a symmetrical theory of nuclear forces.

The situation may thus be summarized as follows: the short life-time of neutral mesons can be explained by Sakata and Tanikawa's process, which means that there is an essential dissymmetry in effects responsible for the decay of charged and neutral mesons respectively. Against this picture objections of principle can be raised (divergences). Alternatively, one can use equation 1, which exhibits symmetry with charged meson decay, and replace equation 3 by 2, which on account of the fundamental dissymmetries of the electron-neutrino interaction is not unplausible. The objections raised against the former treatment, moreover, do not apply here; thus it would seem not inappropriate to suggest this possibility, although it must be admitted that the present discussion, because an *un*observability is at stake, is somewhat academic.

Mechanism of Brittle Rupture

FOLLOWING the suggestion of one of us (J. B. M.)[1,2] that the decay of strength of glass with time could be explained on the assumption that the glass consists of an elastic matrix containing small pockets of quasi-viscous material, E. Orowan[3] gave an explanation of the process which was compatible with the presence of 'Griffith cracks' in glass.

Since the extension of a crack is an irreversible phenomenon, the process outlined by Dr. Orowan involves a permanent reduction in strength of glass which has been subjected to a stress exceeding the 'wet strength'. To check this experimentally, we have loaded glass rods for 1,000 minutes with a stress sufficient to break about 20 per cent of the rods, and have then compared the strength of the survivors with a group from the same family which had not been subjected to prolonged loading. In order to make the comparison a true one, we discounted the lowest 20 per cent from the group which had not been pre-stressed, to compensate for the 20 per cent which broke in the pre-stressed group during the loading period.

The strength was determined on a standard testing machine which applied a stress increasing at the rate of 0·25 kgm./mm.^{2}/sec., and which was fitted with an automatic cut-off at the instant of breakage. Special precautions were taken to ensure that the same part of the rods subjected to maximum stress during the prolonged loading also received the maximum stress during the standard strength test (the test being of the bending type). The rods had been carefully selected for quality, and were annealed before use; they had also been wrapped at the point of manufacture to avoid scratches. The following table shows the results of the tests.

		Mean breaking stress	Standa deviati
(*a*)	90 rods stressed to 4½ kgm./mm.^{2} for 1,000 minutes; tested four days after unloading	10·6 kgm./mm.^{2}	1 86
(*b*)	90 rods from same group as (*a*) not subjected to pre-stressing ..	10 4 „ „	1·90
(*c*)	80 rods stressed to 4½ kgm /mm.^{2} for 1,000 minutes; tested one minute after unloading . ..	10·2 „ „	1·75
(*d*)	80 rods from same group as (*c*), not subjected to pre-stressing ..	10·0 „ „	1·82

A difference of 7 per cent in the strength woul be statistically significant, and we are therefo entitled to state that there was no permanent reduction in strength exceeding this amount when glas rods were subjected to a stress of 4½ kgm./mm. for 1,000 minutes. Since the strength of rods mad of this glass falls by as much as 30 per cent when th loading time is increased from 1 minute to 1,00 minutes, it seems that we cannot account fo this by the increase in length of 'Griffith cracks'. S far we have not found it possible to reconcile wit experimental results any theory about the strengt of glass which requires the decay of strength to b due to extension of cracks. This is one of the reason which led to the suggestion that the decay of strengt is connected with the relaxation of a quasi-viscou component of glass, and since this demands that th strength shall be recovered after unloading, due t the recovery of the quasi-viscous component, ou experiment supports the theory.

It should also be noted that the theory demand that all glasses shall exhibit a delayed elastic effect since the quasi-viscous component must cause delay in the distortion of glass under load; furthermore, since both the delayed elastic effect and th decay of strength are supposed to be due to the relaxation of the quasi-viscous component, ther should be a relationship between the rates at whic the two effects occur. Experiments designed t test this deduction are now under way; the chie difficulty being that the delayed elastic portion o the deformation of many glasses under load at roon temperature is very small, being 1 per cent or les of the total deformation. Preliminary experiment have shown that the strain, σ, may be represente over fairly wide ranges of time by the equation, $\sigma = P(k_1 + k_2 \log t)$, where P is the applied stress, the time elapsed since loading, and k_1 and k_2 ar constants. (A similar equation representing the appearance of strain in glass fibres under load wa found to represent experimental results by P. Phillips[4].) It is of interest to note that, on the assumption that the proportion of full-stress concentration achieved at time t is the same as the proportion of full relaxation of a quasi-viscous component at that time, the equation quoted above leads to the expression $P_B(k + k' \log t) = k''$ relating breaking stress P_B with time. It has already been noted by R. N. Haward[5] and F. W. Preston[6] that $1/P_B$ *v.* $\log t$ is substantially a straight line for the two or three glasses already examined.

This relationship, $P_B(k + k' \log t) = k''$, yields the same values of P_B as the earlier one proposed by one of us[1], namely, $P_B - a = b/t^x$, when x is a small number. Over the practical ranges of time available for the experimental work, the two equations lead to almost identical results; but the fact of greatest interest to us at present is the relationship of these results with the delayed elastic effect—a prediction which was made from the suggestion that glass contains a small proportion of quasi-viscous component. This relationship cannot be given accurately until experiments on which we are now engaged are mpleted, but we think the general agreement noted ove to be of sufficient interest to report at the sent time.

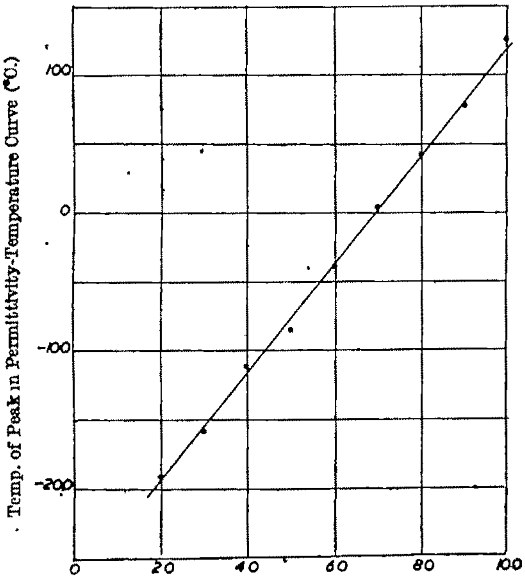
igh Permittivity Crystalline Aggregates

IN view of the recent communication by Dr. B. ul[1], it is desirable to mention that extensive studies the unusual dielectric properties of a range of tanates of perovskite structure and of related subances have been made by a number of research oups both in Great Britain and in the United States ring recent years. We ourselves have been coerating with the British Pottery Research Associaon and Dr. W. H. Taylor, now of the Department Crystallography, Cavendish Laboratory.



The peaked permittivity – temperature behaviour, own for barium titanate by Dr. Wul, is characteris of a range of materials. For the solid solution ries $BaTiO_3$—$SrTiO_3$, the temperature at which e peak occurs is a simple function of the percentage mposition, as shown in the accompanying graph. eak permittivity values of the order of 10,000 have een obtained. The general shape and height of the eak are similar for all the compositions referred to, that Dr. Wul's statement "the dielectric constants the perovskites investigated were found to grow ith the increase of size of the alkaline earth ion" somewhat misleading.

Autoxidation of Linoleic Acid

IN connexion with work on the purification of soybean lipoxidase[1], an investigation was undertaken to identify the primary products formed from linoleic acid when it was oxidized by molecular oxygen with this enzyme or with inorganic catalysts.

In the latter case, methyl linoleate was shaken in oxygen at 37° in diffuse daylight until at most 0·30 mol. oxygen had been absorbed per mol. ester. All absorbed oxygen was present as peroxidic groups (Lea). A strong absorption at 232 mμ appeared during the autoxidation, and increased parallel with the oxygen uptake. The oxidized ester was then directly subjected to chromatographic separation on alumina. Besides unchanged methyl linoleate, two types of peroxides could be separated: (*a*) a more easily eluted mixture of peroxides with a strong ultraviolet absorption ($\varepsilon 232 > 10{,}000$), which on hydrogenation yielded a mixture of primarily monohydroxystearic acids; (*b*) a mixture of peroxides with a negligible absorption above 220 mμ, which on hydrogenation yielded a mixture of hydroxystearic acids, that could be split by lead tetracetate. The consumption of the reagent corresponded to a content of 60–70 per cent dihydroxystearic acid (*c*). A ketonic non-peroxidic entity absorbing at 277 mμ was formed during the chromatographic separation and was eluted with the first fractions of (*a*). Both (*a*) and (*b*) had peroxide values (Lea) of 70–100 per cent of that required for a monoperoxide of methyl linoleate.

The amount of (*a*) plus (*c*) was roughly four times that of (*b*). Approximately the same proportions of mono- and di-hydroxystearic acids were formed when the autoxidized ester was hydrogenated directly and the products separated by chromatographic adsorption.

From the hydrogenated products of (*a*), two pure monohydroxystearic acids were isolated. These two acids, provisionally called M_1 and M_2, constitute the main part of this fraction. M_1 (m.p. 75–76°; methyl ester, m.p. 50–52°) and M_2 (m.p. 75–77°; methyl ester, m.p. 51–52°) give large depressions of the melting point when mixed. In order to identify them we are preparing a number of isomeric monohydroxystearic acids and have so far prepared the 10- and 12-isomers, which are not identical with M_1 and M_2.

We have now obtained melting-point samples of the acids (kindly supplied by Dr. Roger Adams, University of Illinois, Urbana, Ill.) prepared by Tomecko and Adams[2]. M_1 has been identified with 13-hydroxystearic acid and M_2 with the 9-hydroxy acid by the mixed melting point of acid and esters. Both give large depressions with the other isomers available.

These results seem to indicate that the oxygen was primarily formed a hydroperoxide group at C_{11} between the double bonds of methyl linoleate (I) in accordance with the theories and results of Rieche, Hock[3], Criegee[4], Farmer[5] and others. The 11-hydroperoxide (II) rapidly rearranged to a mixture of $\Delta^{10:11;\ 12:13}$ 9-hydroperoxido (III) and $\Delta^{9:10;\ 11:12}$ 13-hydroperoxido octadecadienoic acid methyl ester.

I. $CH_3(CH_2)_4CH{:}CH\ CH_2.CH{:}CH.(CH_2)_7COOCH_3$
(13) (12) (11) (10) (9)
II. $.CH{:}CH\ CH(OOH).CH{:}CH.$
III. $.CH{:}CH.CH{:}CH\ CH(OOH).$
IV. $.CH(OOH).CH{:}CH.CH{:}CH.$
V. $.CO.CH{:}CH.CH{:}CH.$

The conjugated double bonds of these rearranged peroxides would explain the appearance of the absorption at 232 mμ and they would on hydrogenation yield 9- and 13-hydroxystearic acid.

The ketonic entity absorbing at 277 mμ that was formed during the chromatographic separation was probably the doubly unsaturated ketone formed from any of these peroxides by dehydration on the alumina, for example, V.

The peroxides in fraction c yielded on hydrogenation high proportion of α-glycolic hydroxy-acids. This might either indicate that the oxygen was to a minor extent directly added to a double bond (cf. Atherton and Hilditch[6]) or that secondary oxidation of the conjugated double bonds had occurred. The point cannot be decided until further work has been carried out on this fraction.

Furthermore, the potassium salt of linoleic acid has been oxidized in aqueous solution with soybean lipoxidase at 37°. Under these conditions one mole of oxygen can be absorbed per mole of acid in a few minutes. From the hydrogenated reaction product 9- and 13-hydroxystearic acids have also been isolated.

The enzymatic oxidation of linoleic acid with lipoxidase thus seems to follow the same course as ordinary autoxidation.

Primary Degradation Products of Mepacrine in Human Urines

IN a previous note[1] it has been reported that 2-chloro-5-amino-7-hydroxyacridine is to be found in the urines of mepacrine-taking subjects. We have now subjected such urines to a separation technique based on that applied by Scudi and Jellinek[2] to the urines of dogs.

After chromatographic purification on alumina and elution with water or dilute acid, we have obtained solutions in which we have been able to demonstrate the presence of the compounds 2-chloro-5-amino-7-methoxyacridine (II) and 2-chloro-5-(δ-diethylamino-α-methylbutylamino)-7-hydroxyacridine (I), as well as 2-chloro-5-amino-7-hydroxyacridine (III). These compounds have been identified by measurements of their half-wave (reduction) potentials, in buffered solutions, by means of the Cambridge polarograph and comparison with the potentials of authentic specimens determined under similar conditions.

Fuller details of the work will be published elsewhere; in the meantime, we select data sufficient to establish the correctness of our conclusions. It will be noticed that the diagnostic value of the half-wave potential is considerably enhanced by the fact that acridines show two stages in polarographic duction, each of which, at a particular pH, is ch acteristic of the particular derivative.

Below we give, as E_1 and E_2, the half-wave pote tials of the respective acridine derivatives, the fi being mepacrine itself. E_1^A, E_2^A, $E_1^{B_1}$, etc., refer the potentials of the urinary products obtained frc the fractions A, B_1, B_2 and C of the Scudi and Jellin procedure (*loc. cit.*).

Compound	Buffer pH		Half-wave potential
 Mepacrine	pH 7·3	E_1	−1·12

Instability of Dienœstrol and Stilbœstro Solutions

WHILE investigating the metabolism of syntheti œstrogens, we encountered anomalous results durin assays of œstrogenic potency which led us to believ that dienœstrol was unstable in solution. Serie assays carried out on standard solutions of dien œstrol and stilbœstrol have shown the suppositio to be correct.

Solutions of dienœstrol (1 µgm. per ml.) were pre- red in distilled water, $N/500$ hydrochloric acid, d $N/500$ caustic soda, and assayed at intervals cording to the standard method of this Institute vice-daily injections for three days into groups of -20 spayed rats and recording the proportion that go o œstrus or full pro-œstrus within two days of the t injection). The results in Table 1 show that the id and alkaline solutions deteriorated more rapidly an the neutral solution. Polymerization is a possible planation of the change, and this suggestion is pported (though not proved) by the facts that the s of activity in a neutral solution of dienœstrol greatly hastened by the addition of a trace of drogen peroxide but is inhibited by the addition hydroquinone (1 µgm. per ml.). The doses used the assays have been high—3 µgm., representing ree to six times the ED 50 for dienœstrol.

* Dose calculated on stilbœstrol originally present.

Similar tendencies for the biological activity of lbœstrol to deteriorate have been demonstrated. ere again, hydrogen peroxide hastens the loss of tivity and hydroquinone has a stabilizing effect able 2).

The numbers of animals used have been too small allow an accurate estimation of the rate of decom- sition of either substance to be made. Experiments e in progress to obtain more quantitative data ich will be published elsewhere.

Similar results have been arrived at independently F. L. Warren and F. Goulden[1], using the Dinge- anse[2] method of chemical estimation of the com- unds.

These facts mean that the results of assays made dienœstrol or stilbœstrol solutions that are not shly prepared will be low, as will be estimates of e excretion of these compounds where their in- bility in biological liquids has not been taken into count. Although it is not expected that solutions natural œstrogens or of hexœstrol will show similar anges, their stability is also being investigated.

Parathyroidectomy and Lactation in the Rat

So far as we are aware, no accurate study of the effect of parathyroidectomy on lactation has yet been made, though Chandler[1] noted that the young of parathyroidectomized rats were often smaller than normal, suggesting that lactation was impaired. In the rat, thyroidectomy entails removal of the two parathyroids, one of which is embedded in each lobe of the thyroid; but the marked decline in lactation which some workers[2,3,4,5] have reported following thyroidectomy in the rat has usually been attributed to loss of the thyroid, since symptoms of tetany are generally not seen in rats thyroidectomized during lactation[3,4,5]. However, the results of Folley, Scott Watson and Amoroso[5], who found that lactation could be partially maintained in thyroidectomized rats by parathyroid extract, suggested that the impairment of lactation following thyroidectomy may be, at any rate partially, due to loss of the parathyroids. If this were true it would seem possible that those workers[6,7] who found that thyroidectomy had no effect on lactation used a strain of rat in which accessory parathyroids are the rule rather than the exception as is generally believed[8].

We have recently had an opportunity of investigating directly the effect of parathyroidectomy on lactation in the rat, using rats from the same colony and similar experimental methods as in previous lactational studies[9]. Six normally lactating rats were parathyroidectomized on the fourth day of lactation by a technique slightly modified from that of Richter and Birmingham[10]; three control rats were subjected to a sham operation. The growth-rates of the litters of all except one of the parathyroidectomized rats underwent a marked decrease soon after the operation (see graph and table). In constructing the growth-curve reproduced, the data for the litter of the exceptional rat, which continued to grow at a normal rate (see table), were omitted.

Treatment	No. of rats	No. of young on 4th day of lactation		Mean wt. of young (gm.) on day of lactation			Percentage of young alive on day of lactation

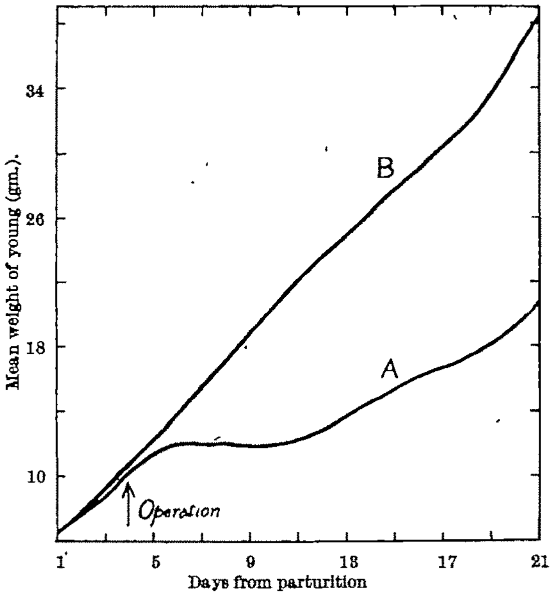
Thyroidectomy*	6	19	25	10·0	13·4	19·0	100	89	66

* Data from Folley[2].

Owing to the fact that these were surplus rats from another experiment, it so happened that one of the control and two of the parathyroidectomized rats received a high-protein diet, which we have found to exert a slightly deleterious effect on lactation, while the rest received the normal stock diet[9]. Analysis of the results for individual rats clearly showed, however, that this factor had no effect on the conclusion to be drawn from this experiment, namely, that parathyroidectomy caused a marked decline in, but not complete cessation of, lactation. This conclusion is, of course, as in all experiments of this nature, subject to the proviso that the only criterion at present available for measuring the milk yield of laboratory rodents—the growth-rates of litters—is a valid one.



CURVE *A* · GROWTH-CURVE OF THE LITTERS OF FIVE PARATHYROIDECTOMIZED RATS, CURVE *B*: GROWTH-CURVE OF THE LITTERS OF THREE SHAM-OPERATED CONTROLS.

At the end of the experiment the rats were killed and the thyroids sectioned serially and examined for parathyroid tissue. None was found in any parathyroidectomized rat, including the anomalous animal. It seems reasonable to assume that this rat alone of the group possessed sufficient accessory parathyroid tissue to support normal lactation. In this connexion it may be recalled that accessory parathyroids were previously found in 17·2 per cent (approximately 1 in 6) of a group of rats from the same colony[5]. In accordance with previous findings with thyroidectomized rats, no symptoms of tetany were seen in these rats after parathyroidectomy.

There is some evidence (see table) that the effects on lactation of parathyroidectomy are scarcely less severe than those of thyro-parathyroidectomy[2]; but it would not be safe to conclude that the loss of the thyroid alone would have no influence on milk-yield, since more complete inhibition of lactation following thyro-parathyroidectomy was noted in a subsequent experiment[5], in which, however, the growth of the young prior to the operation was slightly sub-optimal. It is planned to investigate this aspect of the subject further.

We are indebted to the Agricultural Research Council for a research grant to one of us (A. T. C.), and to Dr. S. K. Kon for the facilities of his rat colony.

Nature of the Gram-positive Complex In Micro-organisms

IN a previous communication[1] it was suggest
that the Gram-positive material in micro-organis
is a high-molecular complex formed by the combin
tion of a reduced basic protein in the cell cyt
skeleton with magnesium ribonucleate. We ha
now succeeded in extracting from various organis
the Gram-positive complex which has the essent
characteristics of a magnesium-containing nucle
protein, the protein constituent of which appears
be of a novel type and to differ particularly fro
known histones and protamines. All attempts, usi
methods described in the literature[2,4], to extra
basic proteins of the histone or protamine type fro
the highly resistant cell cytoskeletons failed to yie
more than traces of compounds having a high-bas
amino-acid content.

The method of obtaining the complex from Gra
positives involved a relatively short autolysis of t
cells at pH 8 and 37°, followed by adjustment of t
centrifuged supernatant to pH 5, at which point
precipitate was thrown down. This consisted
nucleoprotein which was purified by reprecipitati
methods and when fixed on a slide stained intense
Gram-positive. The dye-retaining nucleoprotei
from yeast and *Cl. welchii* have been examined
some detail. The material from yeast readily di
solved in aqueous solution at pH 7 had N, 14·
purine N, 2·9; P, 2·6; ribonucleic acid, *c.* 25 p
cent, and contained —SH groupings. On heating
neutral aqueous solution of the nucleoprotein at 6
for a short time, the protein constituent came dow
in denatured form leaving the nucleic acid in sol
tion, a phenomenon which resembled the behavio
of Cohen and Stanley's[3] tobacco mosaic virus rib
nucleoprotein. By a relatively simple procedure
has been possible to dissociate the protein from i
combination with nucleic acid and to obtain bo
constituents in a reasonable degree of purity. Tl
nucleic acid was entirely of the ribo-type. The pr
tein, isolated in the form of its soluble hydrochlorid
was free from phosphorus and pentose, and ha
N, 14·3; arginine, 5·5 per cent; it was readily d
natured on being dried or heated. Neither the pr
tein nor the nucleic acid alone could be stained l
Gram's method; but on re-forming the complex
pH 5, preferably in the presence of magnesium io
and formaldehyde, it again stained strongly Gra
positive. The Gram-positive nucleoprotein from
welchii closely resembled the yeast product in gener
properties. Thus, it was soluble in water at pH 7, h
N, 14·9; purine N, 2·9; P, 2·5 and contained Mg a
—SH groups. It was, however, more difficult to se
arate into its protein and nucleic acid, while tl
latter had the important difference in that it contain
the deoxy- (3·5 per cent) as well as the ribo-ty
(27 per cent). The dissociated protein constituent ha
N, 14·3 per cent, and contained —S—S— links.

In order to examine the dye-retaining properti
of protein nucleates stained by Gram's method,
number of 'artificial' complexes were made by addi
basic proteins such as protamine salts to magnesiu
nucleates at pH 6–7, whereby precipitates containi
both protein and nucleic acid were thrown dow
Typical nucleates made were protamine ribonucleat
clupeine ribonucleate, histone ribonucleate, histo
deoxyribonucleate, etc. When stained, certain
these, particularly the histone deoxyribonucleate, r
tained in some measure the basic dye; but in gene

results were unsatisfactory, and the stained parations were not comparable with the intensely ined bacterial nucleoproteins. It was clear that the Gram-positive complex the linkage of the pro- n with the ribonucleic acid is not of the simple ctrovalent type, and the mechanism of the reten- n of the dye is more fundamental than its mere nbination with a basophilic salt-like molecule; phydryl groups and magnesium ions do appear to y an important but as yet undetermined part.

So far we have not been able, by using an analogous tolytic procedure, to obtain nucleoproteins from am-negatives. By chemical extraction methods, wever, using bile salt derivatives, saline, etc., we ve obtained nucleic acids of both ribo- and de- yribo-types from certain Gram-negatives. Some ctions contained both proteins and nucleic acids, d when solutions of these were adjusted to *p*H 5, ere separated protein nucleates which were able retain the Gram stain in a manner comparable ith that described above for the 'artificial' protein cleates. Thus it appears that this amount of dye- taining character is a non-specific property of such lts which, as isolated from Gram-negatives, we gard as artefacts. It was also of interest to note that, the Gram-negatives so far examined, the ratio of oxyribonucleic to ribonucleic acid is consider- ly higher than in Gram-positives. Thus we con- der that there are fundamental differences between e basic proteins of Gram-positives and Gram- gatives, and between their mode of combination ith nucleic acids; so that an understanding of these desirable in order to give an insight into the mech- nism of the selective attack of some antibiotics.

Mirsky[4] has pointed out that in deoxynucleo- stones the nucleic acid content is about 40 per cent, hereas in ribonucleoproteins it is of the order of 0 per cent. It will be noted that in our Gram- sitive ribonucleoproteins the amount of ribo- ucleic acid (25 per cent) falls midway between the vo, and it is possible that the protein constituent presents one type of cytoplasmic protein of which it little is yet known. Moreover, this protein pears to differ from that of the histone or protamine pe which was obtained from pneumococcal nucleo- otein[5].

Late Flowering of Horse-Chestnut

DR. JULIAN HUXLEY's letter[1] describing the late owering of horse-chestnut in Paris this autumn rought back to me a vivid memory of autumn 1912. turned up my youthful diary and found this entry: Paris, 3rd September, 1912. The trees are in a queer tate here; the old leaves are dead and falling as in utumn and at the same time new shoots and flowers are borne on the same trees, particularly on the horse-chestnuts in the Champs Elysées." There are few records of weather in the diary but an earlier entry of the same day reads: "We went through the Luxembourg Gardens where the lawns were being watered! (the first time I have seen grass watered this year!)". And on the day before, it had seemed worth while to enter: "It rained a little".

[1] *Nature*, 156, 574 (1945).

THE publication of the note by Dr. Julian Huxley prompts me to record some observations of a similar phenomenon in 1944.

At the beginning of October flowering was noticed on a tree of *Aesculus hippocastanum* at Twickenham, Middlesex, in circumstances similar to those described by Dr. Huxley. This tree had been damaged severely by the frosts of May 3–8. The opportunity was taken of comparing its behaviour with that of two trees of the same species in Sunbury-on-Thames which were defoliated almost completely by blast from a flying-bomb in early August. They were in flower for the first three weeks of October until the blossoms were killed by frost. Small fruits were formed but did not mature. These dates are later than those commented upon by Dr. Huxley.

In 1945, the three trees mentioned produced fewer leaves than usual and very few inflorescences. Most of the buds containing inflorescences must have been used in the autumn flowering.

It is interesting that, although the defoliation of the frost-damaged tree was in May and the bomb-damaged trees in August, all were in flower together in October. Similarly the trees observed by Dr. Huxley were damaged in spring but did not flower again until the autumn, the buds opening at the usual time for leaf-fall.

The mild autumn weather experienced in 1944 may be connected with the second flowering, as this was seen, also, at Sunbury-on-Thames in a species of *Aesculus carnea* Hayne which was not noticed to be damaged in May. It would appear that it is the already defoliated condition of the trees of *Ae. hippocastanum* at the usual time for the commencement of leaf-fall which stimulates the opening of the buds at that time, the production of new leaves and inflorescences in the buds proceeding at the same rate during the summer whether mature leaves are present or not. A comparison between the autumn condition of such a tree and that of a normal tree in the similar temperature and light conditions of spring is tempting.

In view of the fact that some of the species of *Aesculus* flower normally as late as August it would be interesting to observe the behaviour of those trees of European, Asiatic and American ancestry which are collected close together, in virtually the same environment, at the Royal Botanic Gardens, Kew, in any season when second flowering takes place.

THE INDIAN STATISTICAL INSTITUTE

THE continued activity and growth during the war period of the Indian Statistical Institute is a striking example of the benefits which may flow from the stimulus of war conditions, when individual initiative is unhampered in putting itself at the service of Government and to meet the needs and deficiencies of existing official organization. Perhaps nowhere than in India have the prevailing conditions been more propitious, or the need greater, for the active use of agencies run at private risk for public purposes.

The Institute, as it has now developed, has many facets: on the educational side equally as a training ground for computors and routine statisticians, and as a centre of postgraduate research in the most far-reaching branches of the mathematical theory of statistics and experimental design; as a professional institute and learned society bringing together all schools of thought in Indian statistics; as an agency employed by departments of Government and advisory bodies, in the essential work of collecting, scrutinizing and digesting the facts upon which administrative decisions must depend. The achievement of co-operation among the many able men needed to guide these various activities has been the work of an applied mathematician, Prof. P. C. Mahalanobis, formerly professor of physics, acting as honorary secretary to the Institute. He was this year elected fellow of the Royal Society.

There can be no doubt that accurate knowledge by the Government of Bengal of the amount of rice available in the Province would have obviated the food crisis of 1943, in which approximately one million lives were lost, by forestalling panic and cutting the ground from under the food speculators. The story is told in the report for 1943–44:

"The most notable progress in the year under review was achieved in the sample survey of crops. It would be remembered that work was started on a small scale with a total expenditure of about Rs. 7,000 on an exploratory survey of the jute crop in Bengal in 1937. This was the beginning of a five-year scheme for the improvement of jute statistics which was financed jointly by the Indian Central Jute Committee and the Government of Bengal. The sampling technique, developed in the course of a gradually expanding series of surveys culminating in the full scale provincial work of 1941, which demonstrated beyond dispute the possibility of securing by this method a final estimate of jute acreage with a margin of error of only two or three per cent at a cost of one-fifteenth or one-twentieth of that of a complete enumeration. A general account of the five-year scheme with discussion of theoretical foundations was given in a memoir prepared by the Hon. Secretary in 1942 which is being published in the *Philosophical Transactions* of the Royal Society of London.

"The Hon. Secretary had been pressing from the very beginning of the five-year scheme in 1937 for the extension of the method to cover paddy and other important crops in Bengal. Each year from 1938 to 1942 he repeated his efforts but without success. In 1942 the Indian Central Jute Committee had expressed their complete satisfaction with the method of the sample survey and had recommended its continuance by Government in future. The Government of Bengal however decided at first to discontinue the work but subsequently revoked their decision a asked the Hon. Secretary at the end of March 19 to proceed with the Jute survey. By this time good portion of Burma had been occupied by t Japanese, and the supply of rice from that count had been cut off. Apprehending a serious deterio tion in the food situation (not because of the physi volume of the import which was small but becau of the possible effect on prices) the Hon. Secreta submitted a definite scheme to the Government India at the end of March 1942 for extending t sample survey to cover the paddy crop in Beng In the course of the next few months he also d cussed the question with a large number of offici in Bengal but all his efforts failed completely. In t absence of reliable statistics both the provincial a the Central Governments were left entirely in t dark regarding the supply position of rice at the e of 1942. This made it impossible for Government pursue a consistent food policy on any objecti basis. The weakness of the statistical position w thus an important factor in bringing about t deplorable food crisis in Bengal in 1943."

It was not, therefore, until after the famine th the Institute was enabled to show what its organiz tion could do with the immense problem of sampli the 70,000 square miles of agricultural Beng Adequate accuracy in areas under crops is much mo difficult to attain than is yield for unit areas. Son 59,000 grids each of 2·25 acres, chosen on a syste of stratified random sampling, were needed f Bengal, the whole being divided into zone cells sixty-four square miles and sub-cells of one squa mile, approximately the area occupied by a sing village. A feature of great importance for India conditions, and worthy of study elsewhere, is t duplication of the system in interpenetrating ne works, so that entirely independent pairs of estimat are available for each area. This not only facilitate the administrative checking of gross negligence, misunderstood instructions, but also enables the pr cision of the final estimate to be assessed as it real is by including all causes, human as well as physica which contribute to inaccuracy in the result.

There is perhaps no other organization in whic practical and theoretical work are more thorough integrated. The combinatorial investigations of R. Bose and A. Bhattacharya and the studies of mult variate distributions of Mahalanobis and S. N. Ro supply not only the general plan but also ver detailed guidance to the two hundred or so worke of the field and computing staffs.

EXCAVATIONS AT HYRAX HILL, NAKURU, KENYA COLONY

ALTHOUGH uncertainties in detail may sti exist, the general structure of the prehistor story of Kenya as laid down by Dr. L. S. B. Leake is now accepted by most prehistorians. The variou climatic changes that have occurred and their co relations with the more important cultures found a also clear. Following on a major pluvial phase calle Gamblian and correlated with the Kenya upp palæolithic, there were two merely wet phas separated by a dryer period. These are know respectively as the Makalian and the Nakuru w phases. They are post-palæolithic in age, and th latter is not of great antiquity.

Mary D. Leakey, in a paper entitled "Report on
) Excavations at Hyrax Hill, Nakuru, Kenya
lony, 1937–1938" (*Trans. Roy. Soc. S. Africa*, 30,
. 4), describes excavations made at sites on an
inence which was under water during the period
vered by the last major pluvial (Gamblian), and
ng the sides of which occur beach-levels of the
bsequent wet phases. Correlation of the archæ-
gical and geological records is therefore simple. A
mber of sites, including some stone-walled en-
sures and a low mound, were investigated, as well
a group of pit dwellings. There were found : (1) a
olithic occupation site and cemetery, (2) a Gumban
eolithic) pit-dwelling village, and (3) a later, prob-
ly not very ancient, level connected with the
ne-walled enclosures and associated burial pits
d with an industry which shows the influence of
ab traders.

The neolithic occupation site lies on the 335-ft.
ach (Makalian) and is therefore subsequent to its
rmation ; the Gumban pit-dwelling is somewhat
unger in age and contains an industry (Gumban *B*)
ich is well known elsewhere and has been assigned
the maximum period of the later (Nakuru) wet
ase. From the earlier neolithic levels there were
ought to light no less than eighteen skeletons—a
mber female—in contracted burials. These are
scribed in detail by Dr. Leakey.

The associated industry clearly shows its upper
læolithic origin, for it must be remembered that in
ast Africa there were no devastating climatic
anges of the magnitude of those which obtained in
urope ; cultures were not swept away but ripened
d went to seed ; the past continued to influence
e growth of the present much more than was the
se in Europe. Thus in the levels above mentioned,
ere were found a whole series of obsidian tools
early derived from normal Kenya upper palæolithic
pes. In the Gumban levels there were stone bowls
d pottery typical of the Gumban *B* neolithic.

The report contains 409 pages and is well illustrated.
l concerned in the post-palæolithic cultures of
enya will find it very interesting.

M. C. BURKITT.

AUTOMATIC CONTROL AND RECORDING IN CHEMICAL AND OTHER PROCESSES

THE Institution of Chemical Engineers, the
Institute of Physics and the Chemical Engineering
coup of the Society of Chemical Industry made
rangements more than a year and a half ago to
ld a joint conference in the autumn of 1944 on
cording and controlling in the chemical industries.
he incidence of flying bombs and of rockets, how-
er, made it inadvisable to gather together a large
umber of key technicians in London at that time,
d the conference was postponed indefinitely. This
s proved to be a fortunate circumstance ; for the
nference was held on October 19 of this year, when
e industries interested were not completely occupied
th war-time requirements, but were turning their
tention once again to the problems of ordinary
mmercial production. In consequence, the con-
rence has been held at a time when industry is not
erely aware of certain technical deficiencies but also
actually planning to do everything possible to overcome them. That the subject of the conference is of vital interest to the chemical industries, as indeed it is to all industries, was shown by the remarkable attendance, the lecture theatre at the Royal Institution being filled and almost over-filled. Apart from all other benefits which accrue from a conference of this kind, the personal contacts which are made between the makers and users of instruments provide ample justification for holding it, and it was a happy thought on the part of the organizers to arrange that the instrument firms should hold private exhibitions of their instruments on the following day.

In the opening address to the conference, given by the president of the Institute of Physics, Sir Frank Smith, two main points were made. The first was the interesting one that although in industry the scientific instrument is usually regarded as the handmaiden of industrial processes, experience shows that the emergence of a new type of instrument has often been responsible for the birth of a new industry. There is, for example, a great industry now in existence catering for the requirements of radar, and it is indisputable that radar, and the industry associated with it, could not and would not exist unless an instrument were available for measuring time intervals smaller than one millionth of a second. Some decades ago, Sir J. J. Thomson devised the first instrument capable of achieving such measurement. This was the cathode ray tube, which later became the cathode ray oscillograph. Without this instrument, and without also the wireless valve which was a development of an instrument (the one-way rectifier of Sir Ambrose Fleming), there could not have been any radar nor, in consequence, the great new industry which has developed around it. Equally spectacular examples could be cited; but it is probably true that nearly every big advance in industry has been the result of knowledge obtained in the first place by the use of a new instrument. There is, therefore, every incentive for industry to be instrument-conscious, apart from that arising from the benefits obtained by the use of instruments which is ancillary to industrial processes.

Britain has been warned, and is acutely aware, that the maintenance of its standard of living is dependent upon an increased export trade. The achievement of an increased export trade is dependent upon our ability to produce articles of exceptional and standard quality at competitive prices. The material articles which can be exported can be classed either as special products or as articles capable of being produced by mass-production methods. It is in the production of this latter category that a realization of the necessity of industrial instrumentation is essential. Only by the complete control of processes can an exceptional quality of product be made standard, and only by the avoidance of waste and the lowering of costs resulting from control can competitive prices be offered.

In some general observations on the use of recorders and controllers, the director of the British Scientific Instrument Research Association, Mr. A. J. Philpot, pointed out that the general industrial structure of Britain, with its preponderance of relatively small concerns, has been favourable to the creation and maintenance of a system based on the maximum use of individual craftsmanship and a large exploitation of personal knowledge and experience. Such a system served us well during a long period when industrial processes were relatively static; but the tempo of industrial progress has so increased, and the changes in industrial methods have become so rapid, that it is now essential that scientific investigation and observation should permeate the day-to-day carrying out of processes, and that in any industrial concern the appropriate knowledge must exist which will enable rapid and useful application to be made of any relevant advances in applied science. The use of instrument recorders and controllers is the prime means of ensuring that such observation and such accumulation of knowledge can be made.

There is little virtue in the mere installation of instruments unless steps are taken to see that the scientific method shall be applied to their use; the installation of instruments may eliminate a large amount of human error, but the whole purpose of the instruments may be defeated unless they are in the charge of technicians who understand the principles of their working and fully appreciate the existence of instrumental errors, which may vary from day to day and with changing physical conditions. Since recorders and controllers are based on physical principles, it would seem logical that the wide introduction of these instruments into industry should be accompanied by an extended use of physicists by industry. It is doubtful whether enough physicists exist to fulfil the requirements of industry, and, in any event, it may well be that the physicists required should have some special instruction and practical technical experience outside the normal university course in physics. While it is to be hoped that facilities for technical education of this type will be available in the future, every encouragement should be given to the younger technical personnel in industry to take advantage of the newly established courses for national certificates in applied physics.

The use of automatic control in the oil industry and in the pasteurization of milk were the subjects of papers by Mr. D. J. Pull and Mr. R. A. Hill, both of which were largely factual statements of the actual systems of automatic controls used in these two spheres. The diverse nature of control is well illustrated by the use of instruments for these two purposes. In the oil industry, when conditions have been achieved such that optimum results are obtained, the paramount need is for a system of control which will prevent any departure from these conditions. An absolute knowledge of, for example, the exact temperatures employed is of secondary importance compared with the rigid maintenance of these temperatures, as only thus can the production of a standard material be assured. In the pasteurization of milk, both an exact knowledge of the temperature and the maintenance of this temperature are essential, since the nutritive value of the milk, and the effectiveness of pasteurization achieved, are vitally dependent upon these factors. The chemical processes of the oil industry are extremely complicated and tend to become progressively more so; and it is evident that the development capacity of instrument manufacturers will be severely strained if instrument design is to keep pace with the control requirements of the industry.

It is perhaps unfortunate that the operation of a controlling mechanism appears to be simple and inexorably exact. The statement, however, that any physical phenomenon, the action of which can be measured, can be used to operate a controller which in turn limits the extent of action of the phenomenon, while generally true, gives no indication of the complications which are inherent in any controll
instrument. This point was well illustrated in t
papers of Prof. K. A. Hayes and Dr. G. D. Pri
which dealt with the mathematical analyses involv
in studying the characteristics of control systems a
of the stability of such systems. The growth in u
by industry of what is commonly called instrumen
tion has been exceedingly rapid, and it is not gen
ally recognized that there is involved in this inst
mentation a new branch of technical science, a
that knowledge of this technology has probab
lagged behind its application. Valuable work on t
subject has been carried out by the Servo Panel
the Ministry of Supply during the War, and althou
the attention of this Panel has naturally been direct
towards the problems of control in military usage,
for example, those inherent in the use of predicto
there is much ground common to these problems a
those connected with the control of industrial p
cesses. It would be a pity if knowledge of the valua
work carried out by the Servo Panel were not ma
available to those responsible for designing, install
and running control systems in industry. If indust
is to make full use of instrumental control, as
undoubtedly must do, then it would appear essent
that the establishment of courses in technical insti
tions in the technology of instrument control shou
be very seriously considered.

In reviewing the proceedings of the Conferen
perhaps the most vivid impression left on the mi
is the general agreement which exists that the tra
ing of physicists is not complete unless it results
students obtaining some knowledge of the m
general applications of physics in industry and,
particular, of the use of physical principles in t
control of industrial processes. It was urged at t
Conference, as indeed it has been urged elsewhe
that the equipment of the ordinary university phys
laboratory might well include examples of instrume
controls, and that in their practical courses studen
might examine the performance and limitations
these systems.

The Conference will have been well justified if
has emphasized the urgent necessity for a mo
general and thorough knowledge of applied physi
and if it has demonstrated that the use of instrume
controls in industry is based on a technical science
which knowledge at the moment is far too limited.

PLANT PATHOLOGISTS IN GREAT BRITAIN

A REPORT, "The Recruitment and Training
Plant Pathologists in Great Britain", which h
been prepared by the Plant Pests and Diseases Co
mittee and adopted by the Council of the Associati
of Applied Biologists, advocates certain improvemen
in the training of plant pathologists with a view to
higher and more uniform standard of proficiency
the time of recruitment into the service. The ter
'plant pathology' in this report is used in its wide
sense to include all disorders of plants, wheth
caused by insects, fungi, bacteria, viruses, etc.

The plant pathological services in Great Brita
have in the main been recruited from graduates
university biological (and to a less extent, chemic
departments who, in the majority of cases, ha
carried out postgraduate research, usually to t
stage of obtaining a Ph.D. degree. This mode

ining is considered to be too narrow, as it does not e proper emphasis to general aspects of crop sbandry, but tends to produce specialists in disease oblems who are insufficiently acquainted with the y-to-day problems of the practical cultivator. commendations for an improved course of training put forward in some detail, the most important which are as follows.

The basic requirement for an entrant into the ofession, whether as research worker or as advisory icer, is held to be the possession of a good university gree in pure science (namely, in botany, zoology or emistry); but this should be reinforced by a post-aduate course of study in plant pathology which ght suitably lead to a diploma in this subject. It suggested that two years would be ample for such course. The students, whether intending to become search workers or advisors, and whether entomogists or mycologists, would follow the same course a considerable period, so that all would possess e same general background, and only in the later rt would there be specialization in the various lines activity. In particular, the importance of condering research workers and advisory officers as uivalent groups and therefore of giving them sentially the same training is stressed. Throughout is course there would be instruction in crop husndry and in research methods, and facilities would provided for bringing all students in contact with e practical problems of plant cultivation.

The carrying out of this scheme would be most itably done in an institute of plant pathology, operly staffed for teaching and for the prosecution applied research; and with good contacts with the dustry on one hand, and with a university on the her. Failing the setting up of such an institute. rtain university departments should be strengthened long the lines indicated.

The need for refresher courses for advisors and search workers, for greater provision of technical sistance, and for the grant of scholarships to cover e period of two years postgraduate training is also dicated.

Copies of the report can be obtained from the resident of the Association of Applied Biologists, r. C. B. Williams, Rothamsted Experimental tation, Harpenden, Herts.

HOSPITAL DIET

N 1943, King Edward's Hospital Fund for London published its first Memorandum on Hospital Diet *Vature*, **155**, 433; 1945). Since then there has been uch constructive criticism. There has been so uch demand for the Fund's first memorandum that e Committee on Hospital Diet which it appointed, e chairman of which is Sir Jack Drummond, has ow issued a second memorandum (obtainable from . Barber and Sons, Ltd., 23 Furnival Street, E.C.4, d.). Everyone who has to cater for groups of people hould read it. The housewife, also, will learn much om it.

In many hospitals, says this second memorandum, e importance of good catering is now recognized; ut in others it is not. The catering department a hospital should be regarded as one of the ospital's main departments. It should be a separte unit, administered by a catering officer, who ould preferably be a dietitian with adequate experience of large-scale catering. Such dietitians are scarce and more will have to be trained. The catering officer should be responsible for the buying and storage of food, the planning of menus and the cooking and service. This would ensure the unification of the responsibility for catering which is essential. Another essential is direct contact with the food markets and trade, and the memorandum discusses in some detail the buying and storage of foods and the keeping of proper records. The catering officer should be responsible to the governing board through the chief executive officer and through a diet and catering committee; he should co-operate also with the medical staff, who often prescribe special diets as a part of their treatment. The catering officer would thus have considerable responsibility and his office should have appropriate dignity. The diet and catering committee would be technical and professional and would have functions, in its own sphere, similar to those of the medical committee, the ultimate responsibility resting with the board of management.

This committee would not, however, abolish the existing personal relation of the nurse and her patients. Nurses would still serve meals; but the meals would be not only nutritionally sound, but also appetizing and attractive. Such small but important details as the introduction of a little colour into a meal tray by the use of a coloured sauce receive the attention which they deserve. A section of the memorandum is rightly devoted to the diet of the doctors, nurses and others whose work creates for them dietary needs different from those of people who work outside hospitals. The ancillary reforms in the training and efficiency of all grades of kitchen staff also receive adequate consideration.

The committee hopes to see the final abolition of the practice of serving in hospitals only one cooked meal a day, so that relatives and friends of patients would no longer have to bring in supplementary foods. It is odd, however, to find that, among such supplementary foods, eggs and fruit are classed as luxuries. The specimen diets, the seven pages of recipes, the sections on menu-planning and storage of food, the wise advice about salads and raw vegetables, the tables of the nutritive values of various foodstuffs and the valuable section on the destruction of food elements, such as vitamin C, by improper cooking, will interest everyone.

The whole memorandum is so free from the fads and nonsense so often associated with brochures about food that it can be thoroughly recommended.

G. LAPAGE.

FORTHCOMING EVENTS

Saturday, December 15

ASSOCIATION OF SCIENTIFIC WORKERS, LEEDS BRANCH (at the Riley-Smith Hall, University Road, Leeds 2), at 2 30 p.m.—Second Conference on "Science and Education". Prof. J. D. Bernal, F.R.S.: "The Policy of the Association of Scientific Workers in regard to Science and Education".

SOCIETY OF CHEMICAL INDUSTRY (Joint meeting of the FOOD GROUP with the YORKSHIRE SECTION of the S.C.I. and the HULL CHEMICAL AND ENGINEERING SOCIETY, in the Lecture Theatre of the Mining Department, The University, Leeds), at 3 p.m.—Mr. J. Pryce Jones: "Honey".

Monday, December 17

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (in the Lecture Theatre, Mining Institute, Newcastle-upon-Tyne), at 6 p.m—Dr W. G. Thompson· "Electronics, their Scope in Heavy Engineering".

ROYAL GEOGRAPHICAL SOCIETY (at Kensington Gore, South Kensington, London, S.W 7), at 8 p.m.—Wing-Commander D. C. McKinley and Wing-Commander R. Winfield "The Arctic Flights of the *Aries*".

Tuesday, December 18

SOCIETY OF CHEMICAL INDUSTRY, AGRICULTURE GROUP (in the Chemistry Lecture Theatre, Imperial College, Imperial Institute Road, London, S.W.7), at 2 30 p.m.—"Role of the Chemist in Dairying". Dr A. L. Provan : "The Chemist and Milk Production" ; Mr. E. V. Anderson · "The Chemist in Milk Processing and Manufacture".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W 1), at 5.15 p.m.—Sir Henry Dale, O.M , Pres.R.S. · "Recent Developments in Chemical Therapeutics", (iii) "Penicillin and other Antibiotics".

EUGENICS SOCIETY (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Dr. D. V. Glass : "Aspects of the Development of Population Policy".

ROYAL ANTHROPOLOGICAL INSTITUTE (at 21 Bedford Square, London, W C.1), at 5.30 p m.—Mrs. K. M. Trowell : "Modern African Art in East Africa".

BRITISH RHEOLOGISTS' CLUB (at the Royal Society of Arts, John Adam Street, Adelphi, London, W.C.2), at 6 p.m.—Dr. E. Preston . "The Flow of Glass".

Wednesday, December 19

PHYSICAL SOCIETY, COLOUR GROUP (in the small Physics Lecture Theatre, Imperial College, Imperial Institute Road, London, S.W 7), at 3 30 p.m —Dr. W. S. Stiles : "Colour Discrimination, the Visibility Curve and the Trichromatic Theory".

ROYAL COLLEGE OF SURGEONS OF ENGLAND (at Lincoln's Inn Fields, London, W C.2), at 5 p.m.—Prof. H. Barcroft : "The Circulation in Human Skeletal Muscle".

SOCIETY FOR VISITING SCIENTISTS (at 5 Old Burlington Street, London, W 1), at 7 30 p.m.—Discussion on "Science in Australia and New Zealand" (Speakers Mr. G. B. Gresford, Dr. C. H Kellaway, F.R.S., Dr. I. E. Coop or Dr. J. C. Andrews, and Dr. F. P. Bowden).

Wednesday, December 19—Thursday, December 20

SOCIETY FOR GENERAL MICROBIOLOGY (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1).

Wednesday, December 19

At 10 a m —Symposium on "Variation of Cells having Bi-Parental Inheritance" (to be opened by Prof C. K. Ingold).

At 2.30 p m.—Symposium on "The Role, Organisation and Maintenance of Collections of Living Micro-organisms" (to be opened by Prof. Johanna Westerdijk).

Thursday, December 20

At 10 a.m —Miscellaneous Papers.

At 2.30 p.m.—Demonstrations.

Thursday, December 20

ROYAL COLLEGE OF SURGEONS OF ENGLAND (at Lincoln's Inn Fields, London, W.C.2), at 5 p.m.—Prof. O. G. Edholm : "The Circulation in Human Skeletal Muscle".

BRITISH INSTITUTE OF RADIOLOGY (in the Reid-Knox Hall, 32 Welbeck Street, London, W.1), at 8 p.m —Mr. M. H. Lupe and Mr. L. A. Kemp . "The Physicist in the Radio-Diagnostic Department".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned :

LECTURER (full-time) IN CHEMISTRY—The Principal, Acton Technical College, High Street, Acton, London, W.3 (December 21).

SENIOR RESEARCH SCIENTIST in connexion with the development of a long-term programme of research on the overseas transport of refrigerated food cargoes, and a CHIEF TECHNICAL ASSISTANT in connexion with research on the overseas transport of refrigerated food cargoes—The Secretary, Refrigerated Cargo Research Council, c/o Australian Tonnage Committee, 88 Leadenhall Street, London, E C.3 (December 22).

LECTURER IN CHEMISTRY (chiefly Organic) to Honours Degree standard, in the Constantine Technical College—The Director of Education, Education Offices, Middlesbrough (December 22).

TEACHER (full-time) OF ENGINEERING WORKSHOP PRACTICE—The Principal, Aston Technical College, Birmingham (December 22).

SCIENTIFIC OFFICER, and a SENIOR SCIENTIFIC ASSISTANT, in the Department of Agricultural Economics—The Secretary and Registrar, The University, Bristol (December 29)

ASSISTANT ENGINEER for the Iraqi State Railways—The Ministry of Labour and National Service, Appointments Department, Technical and Scientific Register, Room 670, York House, Kingsway, London, W C.2, quoting E.2150.A (December 29).

LECTURER IN CHEMISTRY at the Military College of Science, Stoke-on-Trent—The Ministry of Labour and National Service, Appointments Department, Technical and Scientific Register, Room 670, York House, Kingsway, London, W.C 2, quoting F.4645.A (December 31).

DEPUTY CHIEF ENGINEER—The Engineer, River Nene Catchment Board, Engineer's Office, Priestgate, Peterborough, endorsed 'Deputy Engineer' (December 31).

RESEARCH MYCOLOGIST to be attached to the Plant Protective Chemistry Section for investigations on laboratory and greenhouse methods for the bio-assay of fungicides, an ENTOMOLOGIST (resident in Scotland) to assist research into the causes and control of crop failure in the Scottish raspberry growing areas, a RESEARCH ENTOMOLOGIST to be attached to the Plant Protective Chemistry Section for investigations on laboratory and field methods for the bio-assay of insecticides, and a HORTICULTURIST to carry out research at East Malling and in Scotland into the propagation and cultivation of Small Fruits, with particular reference to the raspberry—The Secretary, East Malling Research Station, East Malling, Maidstone, Kent (January 1).

CHAIR OF ZOOLOGY in the University of Cape Town—The Mini of Labour and National Service, Appointments Department, Techn and Scientific Register, Room 670, York House, Kingsway, Lond W.C 2, quoting F.5269 A (January 1)

ASSISTANT LECTURER, Grade III, IN THE DEPARTMENT OF MET LURGY—The Registrar, The University, Liverpool (January 1).

CHEMIST IN THE DEPARTMENT OF DAIRY CHEMISTRY—The Secreta National Institute for Research in Dairying, Shinfield, Readi Berks. (January 1).

LECTURER IN THE CHEMISTRY AND BIOLOGY DEPARTMENT—T Registrar, Municipal College, Portsmouth (January 5).

LECTURER IN ZOOLOGY in the University of Tasmania—The Ag General for Tasmania, Australia House, Aldwych, London, W (In Hobart, January 7).

DIRECTOR OF CHEMICAL LABORATORY—must be F R.I.C. and poss the Branch E Diploma of the Royal Institute (Ref. No F 5248. and an ANALYTICAL SPECIALIST, with wide experience preferably analysis of soils, water, cement and other constructional materia petroleum products, oil seeds and cake, etc. (Ref. No. F.5249. to the Iraq Government—The Ministry of Labour and Natio Service, Appointments Department, Technical and Scientific Regist Room 670, York House, Kingsway, London, W C 2, quoting t appropriate Ref. No. (January 8).

TELECOMMUNICATIONS ENGINEER (Ref. No. D.1606.XA), a Ci ENGINEER for appointment as Area Engineer (Ref No. E.2127.X and MECHANICAL ENGINEERS (2) for Shift Work operating Stea Driven Electrical Power Plant (Ref No. C.2965 XA), by an Company in the Middle East—The Ministry of Labour and Natio Service, Appointments Department, Technical and Scientific Regist Room 670, York House, Kingsway, London, W C 2 (January 10).

ASSISTANT LECTURER AND DEMONSTRATOR IN THE DEPARTME OF PHYSICS—The Registrar, University College of South Wal Cathays Park, Cardiff (January 15).

CHAIR OF ELECTRICAL ENGINEERING—The Secretary of Univers Court, The University, Glasgow (February 11)

CHAIR OF AGRICULTURE (Animal Husbandry) in Canterbury Ag cultural College, Lincoln, New Zealand—The Secretary, Universit Bureau of the British Empire, c/o University College, Gower Stre London, W.C.1 (February 28).

LECTURER (Grade II) IN PETROLOGY AND MINERALOGY—T Secretary and Registrar, The University, Bristol (February 28).

MYCOLOGIST, and a BOTANIST, for the Rubber Research Schem Ceylon—The Chairman, London Advisory Committee for Rubb Research (Ceylon and Malaya), Imperial Institute, London, S.W (February 28).

LECTURER IN MEDICAL PARASITOLOGY—The Secretary, Departme of Entomology and Parasitology, School of Tropical Medicine, Pen broke Place, Liverpool 3 (March 1).

LECTURER (full-time) IN THE DEPARTMENT OF MENTAL HEALTH—The Secretary, The University, Aberdeen (March 23).

CROMBIE ROSS CHAIR OF MENTAL HEALTH—The Secretary, Th University, Aberdeen (March 30).

LECTURER IN BACTERIOLOGY—The Registrar, The Universit Sheffield (March 30).

FOURTH LECTURER IN BACTERIOLOGY—The Secretary, The Unive sity, Edmund Street, Birmingham 3 (March 31).

PROFESSOR OF PSYCHIATRY, and a PROFESSOR OF MEDICINE—Th Registrar, The University, Leeds (March 31).

ASSISTANT BIOCHEMIST (graduate) for Clinical Laboratory—Pro Dunlop, Clinical Laboratory, Royal Infirmary, Edinburgh.

SKILLED MECHANICS for medical research workshop—The Directo Radiotherapeutic Research Unit, Hammersmith Hospital, Londo W 12

LECTURER IN THE CIVIL AND MECHANICAL ENGINEERING DEPAR MENT (with Structures as one of the main subjects)—The Secretar Woolwich Polytechnic, Woolwich, London, S.E.18.

LECTURER IN ENGINEERING—The Principal, Leicester College Technology and Commerce, Leicester.

LECTURER IN MECHANICAL ENGINEERING SUBJECTS to High National Certificate standard in the Crewe Technical College—Th Director of Education, County Education Offices, City Road, Chest

SENIOR TEACHER OF MATHEMATICS in the Engineering Departme of the Burton-upon-Trent Technical Institute and Junior Technic School—The Secretary and Director of Education, Education Offic Guild Street, Burton-upon-Trent, endorsed 'T'.

THE FOOD AND AGRICULTURE ORGANISATION

THE work of the Food and Agriculture Organisation of the United Nations is so closely linked in some fields with that of the United Nations Relief and Rehabilitation Administration that the confidence in which this first of the functional organizations of the United Nations was shaped at Hot Springs in May 1943 has naturally been somewhat undermined by the chequered career of the Relief and Rehabilitation Administration and the tardiness of the United States, for example, in voting essential supplies. None the less, the firm pledges which Britain has given to the latter organization and the successful issue of the preparatory conference, which in November led to the constitution of a United Nations Educational, Scientific and Cultural Organisation, are among the pointers which warrant the hope that in the Food and Agriculture Organisation there is another functional association through which science may make an increasingly effective and important contribution to human welfare.

The appointment of Sir John Orr as first director-general of the new Food and Agriculture Organisation will be widely and warmly welcomed among men of science. It is in itself a conspicuous example of the fitness of a man of science for high administrative office ; and it also emphasizes the vital importance of scientific and technical factors in this field of agriculture, nutrition and food supply. The association of Sir John Orr with such a post suggests that in the policy of the Food and Agriculture Organisation the findings of nutritional science and human needs will be kept well in the forefront.

The United Nations Information Organisation has done well, therefore, to issue an account of the new organization*. The Charter of the Food and Agriculture Organisation was signed on October 16 by thirty nations at Quebec and a few days later was signed by the Soviet delegation, and the pamphlet gives a brief account of the work of the Interim Commission from the close of the Hot Springs Conference to the opening of the Quebec Conference on October 16 last. The Interim Commission consisted of representatives of the forty-four United and Associated Nations under Mr. L. B. Pearson as chairman, and was working at Washington six weeks after the close of the Hot Springs Conference. It has recruited a small international secretariat, and prominent scientific men and economists from many countries have given freely of their time and expert knowledge. For the first few months, the Commission concentrated on drafting a constitution and on preparing the First Report to Governments on the scope and functions of the Organisation. In this work it was aided by two panels of experts, one on the scientific aspects of food and agriculture and the other on the economic.

The Declaration drafted by the Interim Commission pledges the Governments adhering to the Organisation "to work separately and together to the end that want and the fear of want shall be progressively abolished", and for this purpose to take all measures within their power "to raise the level of nutrition and the standard of living of the peoples under their jurisdiction"; and "to improve the efficiency of agricultural production and distribution". In essence, the Food and Agriculture Organisation will attempt to marry nutrition with agriculture. On one side it is a direct outcome of the advances in the knowledge of nutrition which has characterized the last two decades. Equally, however, the Hot Springs Conference approached the problem of agricultural production in the light of the human and universal need of freedom from want, and was therefore able to bring the whole economic problem under review and to place the individual needs of producers and consumers of particular commodities in their proper perspective.

---

* Towards a World of Plenty. (United Nations Information Organisation.) (London : H.M. Stationery Office, 1945.) 4*d*. net.

This was probably the greatest achievement of the Hot Springs Conference, and the reports prepared for the Quebec Conference further attest the objective approach which the Organisation is making towards the whole question and the importance of the technical and scientific contribution, from the agricultural scientific worker, the economist and the expert in nutrition. A Committee on Agricultural Production, of which first Prof. J. A. Scott Watson, and later Mr. Peters of the Netherlands, was chairman, has prepared a report on the major problems facing the farmers of the world and has made recommendations for concrete programmes of work to be undertaken by the Organisation. Under Dr. F. Boudreau, a Committee on Nutrition and Food Management is reporting on the way experience gained in war can be utilized for purposes of peace, while a Committee on Forestry, under Dr. Graves, has presented a report on world forestry and primary forest problems, and is now considering the more immediate world problems. A Committee on Fisheries under Dr. Finn, the Canadian Deputy-Minister of Fisheries, as chairman, is reporting on the fisheries of the world, and a fifth technical committee, on statistics, under Dr. Becker, is considering ways in which statistical information about food, agriculture, forestry, and fisheries can be improved.

The scientific and technical contribution from these committees is one sound reason for appointing a scientific man of outstanding administrative ability to take charge of the whole organization; and Sir John Orr's appointment may be taken as evidence of the desire of the members to see that the Organisation sets itself severely practical tasks, and that in particular it serves as an adequate and effective source of technical and scientific advice to whatever political body may be authorized by the United Nations to take executive action. 'It is of the first importance that the Food and Agriculture Organisation should secure a position of authority as an impartial source of information and advice in agricultural and nutritional matters, and the presence of a leading man of science as its director-general affords a guarantee that this primary objective will be steadfastly pursued.

There can be no question as to the value of the work which the new Organisation could do in spre ing knowledge of the best agricultural practice a technique, and in acting as a clearing house information, both practical and statistical. T backward condition of agriculture in so many pa of the world indicates sufficiently the wide field f improvement here, and if the new Organisati merely provided a meeting ground for the expe and a forum for the discussion of matters of comm concern, it might still be invaluable in furthering t aims of the Hot Springs Conference, irrespective the progress made in organizing economic relatio internationally in more general fields. But besid this, the Organisation can undertake research a lend or negotiate the services of experts for t improvement of agriculture and nutrition. O request, it may review projects for the developme of agriculture involving requests for internation loans, and it may also undertake the drafting conventions for the control of agricultural pests an diseases, the establishment of grades and standard statistical measurements and nomenclature.'

It is not belittling the contribution which th Food and Agriculture Organisation could make t point out that, where development schemes ar concerned, no major results can be obtained withou providing machinery and equipment on a large scal In countries such as India and many parts of Afric the problem becomes one of providing the means fo development, in order that the efficiency of production may be raised from its primitive level. Similarly on the side of nutrition, the elimination of malnutrition and the raising of standards of living mean th alleviation of poverty and provision of purchasin power. Here the Organisation clearly cannot tak the practical steps of subsidizing food consumptio or negotiating agreements with food producers.

The economic measures by which the increased production and purchasing power are to be secured in any particular country are matters for the Government of that country and not for the new Organisation. The value of its advice and the pressure it is able to exert will be all the greater if it can work out scales of priorities for meeting the world's hunger and want which take into account the relative and diverging interests of producers and consumers. If the Organisation, in fact, did no more than find out the size of the world's food requirements and the potentialities of its agricultural production, and then try to bring the two halves of the picture together, the world would still have ample reason to be grateful to President Roosevelt for his initiative in calling the Hot Springs Conference.

To achieve its aims, the director-general will need to see that the Organisation deals only in realities; and no efforts should be spared to achieve increased efficiency, not only in the production of the world's food supplies but also in their distribution. It is understood that before returning to England to settle up his affairs, the director-general instructed the officials of the Organisation to prepare a world-food picture, indicating the world-market situation for the next twelve months of each important commodity and the nutritional situation in every country.

this formidable task the Combined Food Board the United States Department of Agriculture's ce of Foreign Agricultural Relations are assisting. n the statistical side the new Organisation will elop and extend the useful work that was done ore the War by the International Institute of iculture at Rome, and should increasingly provide his field the factual basis for policy and practice ch Lord Woolton, in his recent presidential address the Royal Statistical Society, noted is at present king. But Sir John Orr has already indicated that main problem of the next few years, as he sees is to harness the agricultural productive capacity the Western world, increased during the War, to needs of an Eastern world which is starving but not pay for imports of food; and while the solu- n of that economic problem is a responsibility for her levels, the Food and Agriculture Organisation, a fact-finding body, can do much to demonstrate t its solution is possible. Here again, with a entific man at its head, the Organisation may well expected to lend adequate support to such methods attack as the selection in poor countries of demonation areas and in them to develop all resources the improvement of nutrition by education, cial food distribution schemes and increasing the oduction of foods, particularly protective foods, ch as milk, vegetables, fruit, fish and eggs.

No efforts should be spared to achieve increased iciency, not only in the production of world food pplies, including the development of fresh sources supply—as, for example, the exploration of hitherto touched fishing grounds—but also in their distribu- n. The importance of the latter question was ll emphasized in the Sectional Report (III) of the ot Springs Conference, and the Committee on sheries now at work may well be relied upon to port on the way in which fisheries could be opened in other waters, as has in fact been done during e War, to supplement those in the North Atlantic d North Pacific Oceans which at present provide nety per cent of the world's supply. Particularly ile the shortage of livestock persists, and also in untries where livestock industries cannot easily be veloped, such steps might provide a valuable dition to diets deficient in animal protein.

Important as is this process of fact-finding, research d demonstration of technique and practice, the ientific and technical aspects of the work of the Food d Agriculture Organisation cannot stand by themlves. Even from a wider point of view, the important ntribution to world co-operation, order and underanding which such functional organizations can ake does depend to some extent on the facilities d organization at their disposal for giving effect their findings. For that reason it is important to onsider the exact position of the Food and Agriculre Organisation in the United Nations Organisation a whole and, in particular, its relation to the conomic and Social Council in regard to the trans- tion of policy and findings into action.

For the same reason, while the Food and Agriculre Organisation has commenced by calling on the elp of the Combined Food Board, it should not be forgotten that there is evidence of a tendency to terminate as quickly as possible the agencies for collaboration set up during the War. The work of the Food and Agriculture Organisation will undoubtedly be handicapped by the recent decision to abolish the Anglo-American Middle East Supply Centre. That decision was severely criticized in the course of a recent debate in the House of Lords, and Lord Pethick Lawrence's reply to Lord Altrincham did nothing to allay the misgivings as to the termination of the valuable technical and scientific activities of the Centre. The discontinuance of these activities will undoubtedly be a handicap to the Food and Agriculture Organisation in dealing with the problems of the Middle East. The contraction of the Anglo-American Middle East Supply Centre, from a body capable of developing into a wider international regional organization, into a national one cannot but be a setback to international social and economic collaboration. The Middle East Office set up by the British Government to maintain close personal liaison with its economic and social representatives of the Middle East Governments in Teheran and to work in harmony with the Middle East States can never provide the same effective instrument which the Food and Agriculture Organisation would have found inherent in the Middle East Supply Centre.

The Food and Agriculture Organisation is bound also to be handicapped by the increase in suspicion and distrust which has marked the international situation during the last six months. An important result of the Organisation's work should indeed be the dispelling of such distrust, and the growth of co-operation and mutual understanding on the political plane through the demonstration of the value and practicability of collaboration in the attack on common problems and building up a spirit of friendship and comradeship, the importance of which was so well emphasized in the recent House of Lords debate on the international situation. In that sense the work of the Food and Agriculture Organisation is part of that larger task of re-establishing full freedom of communication and intercourse, and building up that sense of common rather than divergent interests which must form the firm basis of the United Nations or any other world organization.

We may well look, therefore, to the Food and Agriculture Organisation as one of the means for restoring understanding and for promoting the consideration of technical and economic problems from a scientific or professional point of view, free from political bias. To the extent to which it is able to do this and to put politics in the right position of serving and not, as Mr. Bevin indicated in speaking on European relief on October 26, frustrating human welfare, the new Organisation should also promote the cause of world order and peace by dispelling suspicion and enlarging the area of understanding. Clearly, too, if it is to mean anything, the investigations and advice of the Organisation must have important bearings on the formulation of agricultural policy in every country, and the importance of an adequate understanding of the new Organisation and its potentialities is not easily overstressed.

Not all the changing factors of the last two and a half years have, however, been adverse. The Relief and Rehabilitation Administration has done more solid work, in spite of limitations and difficulties, than is often recognized, in dealing with the immediate problems of which even the long-range plans of the Food and Agriculture Organisation must take account. The United Nations Organisation has come into being, and despite changes in the whole political outlook since the San Francisco Conference, the Preparatory Commission has settled to its work with surprising smoothness in London in readiness for the first full meeting of the Organisation in January. More important still, the widespread concern with the present position in Europe, and which has sometimes issued in unreasonable criticism of the activities of the United Nations Relief and Rehabilitation Administration itself, represents a consciousness of the real issues which may well prove one of the greatest sources of strength to both that Administration and the new Food and Agriculture Organisation.

The concern at the threat of famine to Europe manifested in several debates in Parliament has only been strengthened by such statements as that issued by the Ministry of Information dealing with a combined conference in Washington on problems of food supplies and distribution last April, before the close of the War in Europe, and still more by the United States report on Relief and Rehabilitation Needs of Europe and the meeting of the Relief and Rehabilitation Administration Council in London. In a debate on November 16, Mr. Noel Baker, the Minister of State, gave details illustrating the scale of the work of the United Nations Relief and Rehabilitation Administration and the speed with which its organization has responded to varied and unexpected requests; but his speech did nothing to allay the anxiety expressed in the debate that distress in Europe was overtaking the means designed to cope with it and was in danger of reaching an intensity beyond control.

The apprehension of a European breakdown is widespread, and references to it in that debate were the more emphatic because many of the speakers had lately returned from visits to Europe. In an earlier debate, on October 26, Miss Rathbone quoted Sir John Orr's opinion that "in the coming winter in Europe more will die from lack of food and shelter than were killed in the whole five years of the War"; and Sir Benjamin Smith, the Minister of Food, in urging that the supply of additional food for Europe on a scale sufficient to effect any widespread improvement in the situation must be organized on an international basis, had said that the world food-supply prospects for the coming year are seriously disquieting and that in almost all the main foods we are facing deficiencies on the world balance sheet for the next twelve months. When we add to this the limitations placed on the United Nations Relief and Rehabilitation Administration's activities—its statutes forbid it from offering relief to Germany and it is not operating in the invaded countries of western and north-western Europe—and that although the Administration has now reasonable assurance that it will be able to carry on its work until the end next year, delay in voting supply has already depri it of the opportunity of purchasing needed suppl there can be no room for doubt as to the desper seriousness of the situation and that we are s threatened with the victory of destruction.

Unless, indeed, we can avert from Europe—a that must include Germany—the twin menace epidemic disease and social chaos, the Food a Agriculture Organisation will have no opportunity functioning effectively. It is not easy to convin public opinion that everything possible has been do to reduce the danger of disease and social uphea to a minimum. That is one reason why Sir Arth Salter's request for the publication of a White Pa which would help to form sound judgment by givin clear statement both of the needs of Europe and of t resources available to meet them is thoroughly sou

Such a statement, to the extent that it wou enable opinion to be formed on the basis of inco trovertible facts, should be specially welcome scientific workers, who in this field have no sm responsibility in forming and guiding public opinio and above all in emphasizing the physical, ment and psychological consequences of failure to p adequate attention to the nutritional requiremen and of allowing a state of starvation or semi-starv tion to intensify and spread in Germany and Europ But measures to mitigate the existing conditions w not by themselves be entirely adequate. Beyo that, as the Foreign Secretary has emphasized, w have to eliminate the paralysing effect of fear a revival of the German menace. That fear is st the greatest obstacle to confidence and co-operatio and to dispel and eliminate it will be one of th greatest tasks of the United Nations and all i functional organizations. The immediate nee is to prevent the onslaught of famine and econom chaos. While that is being done, the Food an Agriculture Organisation must be formulating i plans for long-term developments; and with i practical objectives, it may well play an importa part in stimulating that international co-operatio which is essential for the well-being of mankind.

THE PLEISTOCENE PERIOD

The Pleistocene Period

Its Climate, Chronology and Faunal Successions. B Dr. Frederick E. Zeuner. (Ray Society Volume 13 for the two years 1942 and 1943.) Pp. xii+32 (London: Bernard Quaritch, Ltd., 1945.) 42*s*.

THERE must be many students who, like mysel being interested in some geophysical problem the Pleistocene period and not satisfied with th conclusions given in the text-books, have turned t the original papers to find exactly the evidence o which those conclusions were based. Anyone wh has had that experience knows how difficult it is co-ordinate the original papers: the evidence is part geological, partly biological, partly cultural; t nomenclature is varied and often of local significanc the evidence is fragmentary, no one geologic section giving the whole history, so that exposures e region have to be matched against those of other, giving play to opinions rather than facts. oraines in one place have to be co-ordinated with ver terraces elsewhere, and these again with raised aches far away ; and one has always to consider the ssibility of tectonic changes of the surface layers. is a great example of not being able to see the wood r the trees, and one has longed for a clear map of e 'woods' with the 'trees' marked in their proper aces and each kind of 'tree' labelled with a name hich does not change from place to place.

The great merit of Dr. Zeuner's book is that it does st that, and I for one must admit that when I had ished reading it I had a clearer picture of the quence of events during the Pleistocene period and the evidence on which that picture is based than I as ever able to get from all the original papers of hich I have read so many. The book is easy to ad for such a complicated subject, is on the whole ell arranged and what is more important it gives the idence largely direct from the original sources. The bliography is full (but why is it subdivided accord-ng to chapters, which makes it difficult to find an em and involves much cross-referencing ?) and the dex is adequate. It is a book that every student of e Pleistocene will enjoy reading, if for no other ason than that for once both 'woods' and 'trees' can e seen in their true perspective.

Having said so much in praise of the book, it must ot be assumed that I agree with all Dr. Zeuner's onclusions. Neither Dr. Zeuner nor anyone else has id the last word on the Pleistocene ; and the main roblem of all, the causes of the great changes in limate, is still open to discussion. Dr. Zeuner has dopted the radiation theory, in which the changes n climate are ascribed to the inequalities and perturb-tions of the earth's orbit ; in fact, it may truthfully e said that the whole book is written around this heory, and it is because he has such a clear aim whether it be true or not) that he has been so success-ul in giving a connected picture. It must be admitted hat he brings a great deal of evidence to support his ontention, and I can quite understand that it will arry conviction to many readers. This is not the lace to discuss the evidence in detail, but I cannot efrain from saying that the supporters of the adiation theory would have been in a stronger osition if it had been found that the first three laciations had each two peaks and the last glaciation hree peaks before Milankovitch had produced his adiation curve and not after. If the evidence for he radiation theory marshalled by Dr. Zeuner stood lone, it would be difficult not to accept it ; but it oes not stand alone ; there are many questions of hysics involved, and these, as I have tried to show lsewhere, give answers which are completely opposed o the theory. On one hand, we have the similarity more or less) of two curves, and on the other ertain objective facts of radiation and energy ; if he latter cannot be reconciled with the theory, then he former means nothing.

As I have already mentioned, one of the great ifficulties in the study of the Pleistocene has been he want of a uniform nomenclature, and this is articularly the case in the designation of the uccessive glacial phases. Having reached the onclusion, by aid of the radiation diagram, that here have been four main glaciations during the leistocene, Dr. Zeuner naturally wished to give hem suitable names. When, forty years ago, Penck nd Brückner were faced with the same problem in the case of the four glaciations they had discovered in the Alps, they reached a very practical solution : they chose for each glaciation a short name taken from a region where evidence of that glaciation was present ; the initial letter of each name was alphabetically in the same order as the series of glaciations starting from the earliest : thus we have Günz, Mindel, Riss, Würm. This committed them in no way to the number of glaciations : if new ones were discovered, new names in the same alphabetical series could be chosen to designate the new glaciation ; there are plenty of vacant spaces. Thus one had a flexible system of names, each short and its initial letter giving its position in the series without excluding possible future additions. The abbreviations G. M. R. W. are concise and unmistakable. For the interglacials Penck and Brückner simply stated the two glaciations between which they fell, thus giving : Günz–Mindel Interglacial, Mindel–Riss Interglacial and Riss–Würm Interglacial, which were abbreviated to G–M, M–R, and R–W, the form of which shows at once that they refer to interglacials.

In choosing his new names, Zeuner has departed entirely from this practical system and has designated his four glaciations Last, Penultimate, Antepenultimate, and Early ; while he designates the three interglacials by the same adjectives. The glaciations are abbreviated to LGl, PGl, ApGl and EGl respectively, and the interglacials to LIgl, PIgl, and ApIgl. With regard to the names of the glaciations : they are not short (Antepenultimate Glaciation is particularly awkward) ; they are not flexible (but by aid of the radiation diagram Zeuner is convinced that no further glaciation will be discovered) and the introduction of the purely English words 'Last' and 'Early' makes the series unsuitable for international use. The abbreviations are particularly unsatisfactory : they are long and there is nothing to show at a glance which are the abbreviations of glaciations and which of interglacials ; for example, ApIgl and ApGl, the former being an interglacial and the latter a glacial ; they should be compared with G–M and M. Considering that Zeuner is satisfied that Penck's four glaciations are identical with his own, why should he not have adopted their names ? They are known to everyone who has read the most elementary text-books on the Pleistocene and they are suitable for use in every language, to say nothing about giving honour where honour is due.

These blemishes, though not small, do not rob the book of its value and I am convinced that many well-read students of the Pleistocene will enjoy, as I did, this bird's-eye view of the most interesting of all geological periods. G. C. SIMPSON.

SELF-SUFFICIENT BIOLOGY

The Directiveness of Organic Activities

By Dr. E. S. Russell. Pp. viii+196. (Cambridge : At the University Press, 1945.) 8s. 6d. net.

DR. RUSSELL'S book is concerned to establish "the conclusion that directiveness and creativeness are fundamental characteristics of life, shared by no inorganic system ; that they are not to be explained in terms of mechanism or of purpose ; that human directiveness or purposiveness in thought and action are a specialised development of the directiveness and creativeness inherent in life" (p. 178). Its purpose is primarily philosophical, to develop a mode of approach to the problems of biology. However, its method, perhaps wisely, is not dialectical; instead of presenting a close train of argument, Dr. Russell indicates, by descriptions of actual examples, what he means by "directiveness". Look, he says, at this regenerating flatworm or developing egg; naïvely beheld, they cannot but seem to strive towards a well-recognized completeness, which is their goal. Consider again the ability of rats to choose, from an array of purified substances, just those which together make up a perfect diet; or the fact that a rabbit, which reacts to a loss of blood by rapidly making more, and to the transfusion of extra blood by getting rid of the excess, nevertheless does neither of these when the loss is rapidly followed by a transfusion; is it not clear, Dr. Russell asks, that it is the need of the organism, rather than any mere physico-chemical stimulus, which determines the animal's behaviour ?

The examples are not always convincing. For example, rats may, as is asserted, be able to pick out for themselves a perfect diet, though the matter is still, I believe, under discussion; but there is no doubt that many other animals cannot. Again, it is difficult to see why, on any reasonable hypothesis, a rabbit should show any marked reaction to an experimental series of bleedings and transfusion which end by restoring the *status quo ante*. But undoubtedly, Dr. Russell can adduce many remarkable biological phenomena which, as he puts it, "are directive towards ends of self-maintenance, development or reproduction". It is difficult not to admit some degree of astonishment at the performance of the minute worm *Microstoma*, which eats *Hydra*, digests all but the sting-cells (nematocysts), and from these selects the varieties with the greatest offensive power (rejecting the other sorts through the mouth), and finally arranges to shuffle these captured weapons through the thickness of its body wall until they reach the surface, where their captor can use them for its own purposes. Such things, to use a cliché, would seem to demand an explanation.

The most unsatisfactory feature of Dr. Russell's book is that he makes no attempt to provide an explanation in other than self-consciously "biological" terms, or even to discuss the explanations which most biologists nowadays advance. "As a philosophy materialism is merely absurd," he asserts, "why then base biology upon it" (p. 2). "For such understanding we require a free biology, with laws and concepts of its own, independent of those of the physical sciences, based upon an objective study of the directive activities of organic agents, unrestricted by the hampering mechanistic hypothesis which is at the back of the causal-analytical method" (p. 4). It may be granted that, whatever a "free biology" may be, specifically biological laws may be quite useful tools of thought. Even the application of straightforward teleology is a quick rule of thumb which often works. And biologists, still without reaching the domain of physics, can rely on a much subtler form of explanation, the appeal to natural selection and the gene.

Russell scarcely mentions either of these fundamentals of biological thought. His only reference to the gene is to classify studies on "the presumed action of genes on development" among the "analytical and disintegrative" physico-chemical investigations which miss the point of "the organism as a living, developing, reproducing whole" (p. 2). This is odd; not only because he allows (p. 158) that those other, one would have thought equally mechanistic, agents, evocators and growth-hormones, do contribu to "a biological account"; but even more becau the modern view of an organism in terms of its gen would seem much more closely akin, philosophicall to his own ideas than was the usual biological pictu of, say, thirty years ago. In his summing up, Russ applies to the living organism a saying of Spinoza's "The effort by which each thing endeavours to persi in its own being is nothing else than the actual essen of the thing itself". As we should put it: the actu essence of the thing itself is to be found in the gen which control its synthetic activities, and whic being capable of maintaining their own specificity b self-reproduction, direct this synthesis always int the paths which are characteristic of that particul organism.

Thus an outlook which stresses that developme and self-maintenance are essential characteristics organisms is in no way in opposition to curre biological thought; but that body of thought ha already gone further than Dr. Russell in relatin these aspects of life, through the concepts of th gene and of natural selection, to the rest of Natur

C. H. WADDINGTON.

TREES AND FUNGI

Trees and Toadstools

By Dr. M. C. Rayner. Pp. 71+18 plates. (London Faber and Faber, Ltd., 1945.) 6*s*. net.

IN this book the general results of investigation carried out over sixty years by a great number o workers is brought together and presented in a forn that should appeal to the layman. It concerns th structure and nutritional relationships between th green and the non-green plant when the connexio is not one of host and parasite but a delicatel balanced relationship in which each partner has share.

The first chapters give an outline of the physio logical processes of green and non-green plants an form a useful introduction to the more comple relationships discussed later in the book. This lead on to a consideration of soil problems and the par played by the micro-fauna and flora in the breakin down of humus.

After this introduction, the author gives a de scription of the toadstools of woodlands with th structural features of their mycelia and the part they play in the soil and in the higher plants.

The later chapters give an interesting account o the fungus roots of coniferous and some other tree and discuss the different types of mycorrhiza an their reciprocal relations with higher plants. Th researches of the author have contributed much t our knowledge of some of these problems; but man of the complex relationships are still unknown an occur not only in plants living in soils rich in humu but also in plants living in the desert where humu is almost absent. Dr. Rayner has given an outlin of the technique necessary in these investigation but has confined her descriptions mainly to th macroscopic features, and this part of the book con tains some excellent photographs from her own an some other sources.

The book gives a well-balanced description of th problem as it stands to-day in regard to conifers, and has provided a new meaning for the layman of th striking display of toadstools in our woodland during the autumn months.

SCIENCE AND RECONSTRUCTION*

By The Right Hon. Sir JOHN ANDERSON, G.C.B., G.C.S.I., G.C.I.E., F.R.S., M.P.

MY interest in science dates back to the early years of this century when, having secured a holarship of sufficient value to enable me to devote year or two to further study abroad, I went to ermany to engage in postgraduate research in ysical chemistry. As it happens, the subject lotted to me was an investigation of the radio-tive properties of uranium, a curious coincidence view of certain activities in which I have recently en engaged.

I had previously, while still an undergraduate in dinburgh, become somewhat concerned about the onomic prospects for specialists in natural science. had noticed, for example, that, apart from school-astering and the limited establishments of the ience departments of the universities, there seemed be no demand in Britain for chemists. Things deed were still much as Lavoisier found them when, ving been condemned to death and being disposed protest, he was informed coldly that the world ad no need for chemists. The War Office assessment the value of trained chemists was expressed in 905 in the offer of a commencing salary of £130 a ear. The only industrial openings one heard of ere occasional vacancies in breweries, and those ually went to well-trained specialists from Denmark. The fact is that, at that time, the staple dustries of Britain still relied on the traditional ethods which had served them well before inter-ational competition became acute. I well remember arning from a schoolfellow the horror with which is father, the proprietor of a famous tannery, had ceived the suggestion that he should introduce a w trained chemists into his tanyard.

However, youth is generally optimistic, and it was ot until I had been at work for some time and ound that my researches were proceeding rather owly—as was bound to be the case from what we ow know of the nature of the subject—that my ind began to dwell again on the prosaic question earning one's living. On reflexion, it was borne upon me that, while my research work was subject no time factor, I was approaching the age limit r entry into the Higher Division of the Civil Service. decided that I had better try for that before was too late, and thus have no occasion to regret aving missed an opportunity that would never recur. n the result, I was awarded a position as a "2nd ass Clerk in the Colonial Office"—such was the nimaginative and even repellent terminology then vogue—and the whole tenor of my life was changed.

This fragment of autobiography enables me to ring out two facts that are not without interest relation to the subject of my address. The first that a good grounding in natural science can be passport to the higher Civil Service, equally with e more usual training in the humanities, or in the istory schools. The second, as exemplified in my wn case, is that public administration does provide ope, apart from the professional or specialist ades, for men with a scientific training. For example, at the beginning of the War of 1914–18, we ere confronted with a serious situation owing to the dden cutting off of all supplies of those synthetic drugs and other fine chemicals and dyestuffs for which we had allowed ourselves to become entirely dependent on Germany. I was made responsible for organizing measures for making good the deficiency so far as the medicinal requirements of the country were concerned, and I was also in continuous consultation with those who were dealing with the explosives and dyestuffs situation. It would take too long to describe the nature of the action that was taken—and taken successfully—to overcome what might have been a fatal handicap in that conflict, but I certainly could not have played my part had it not been for my earlier training. Much more recently that training has again stood me in good stead in discharging the responsibilities that fell to me as Lord President of the Council, leading up to the work on atomic energy to which I am still giving part of my time.

After this rather lengthy introduction, I come to my main subject—science in relation to reconstruction. The restoration of the economic life of Britain, and even the maintenance of the living standards established pre-war, is dependent on building up our industries to a level of efficiency higher than ever before attained. We have, to a large extent, lost the competitive advantage which our mineral resources and sea-power gave us in the halcyon days of last century. It is a further disadvantage that the exports which we must have in order to pay for vital supplies of food and raw materials are so much greater in relation to the corresponding home demand than in the case of either the United States or the U.S.S.R. It is on the quality of our products that we must rely to overcome all disadvantages, and to this end we must build up the finest possible bodies of technicians and make the fullest use of all new developments to which science can point the way. There is no reason to doubt our ability to do this if we know where the obstacles are and show a determination to remove them.

It has long been the fashion to decry our achievements in the field of applied science in the past, though in pure science they are, of course, universally recognized to have been outstanding. This has, no doubt, been in part a pose, exemplifying our well-known habit of self-depreciation. But, in my view, we have, in fact, lagged behind, and for two main reasons—partly because of the dead hand of tradition in our older industries and partly because of prejudice on the part of scientific men themselves. The profit motive was suspect in the higher academic circles before it became an object of attack in politics. The author of one of the most fundamental, and, as it turned out, most fruitful discoveries in electrical science plumed himself on the fact that it could be of no possible use. We must get rid, and we are getting rid, of all that nonsense so far as scientific workers are concerned.

I have said that we have lagged behind in the past; but things were never so bad as is sometimes made out. It is true that, apart from certain traditional lines such as acid and alkali production, chloroform, a few alkaloids and a very narrow range of dyestuffs such as alizarin (turkey red) and azo dyes (khaki) we had no chemical industry at the outbreak of the War of 1914–18. But, as I have already indicated, much was done during that War to overcome the initial handicap, and what has been achieved since—up to the outbreak of the recent War and during its progress—is full of encouragement. That was only to be expected in the case of the great new electrical and chemical industries which had their foundations in scientific discoveries; but the older industries can also show many notable instances of a fresh outlook. Let me give a few illustrations in both categories.

---

* Address before the Manchester Joint Research Council at Manchester delivered on December 6.

In the textile industries, before the War, both uncreasable cotton and unshrinkable wool had been produced as a result of prolonged researches and, during the War, cotton fabrics have been produced in large quantity in which the fibres are so twisted that, on contact with water, they immediately swell and render the cloth waterproof, while at the same time allowing the passage of air.

In the steel and non-ferrous metal industries new processes have been developed and new materials produced for the first time, including many types of alloy steel, and great quantities of magnesium metal from sea-water.

In television we undoubtedly led the world before the War and we are probably still ahead. In the various applications of radio-location, founded upon investigations originally conducted under the Radio Research Board of the Department of Scientific and Industrial Research, we were in almost every instance well ahead of all competitors. Here is a magnificent example of co-operation between science and industry, resulting in the production of power valves working on wave-lengths of a few centimetres—a development undreamt of a few years before.

Between the Wars, Britain gained all the speed records in the air, on water and on land, with British pilots and British machines made in British workshops. We now hold all these records again.

All aeroplanes are fitted with perspex—the transparent non-splintering plastic produced in Britain—and, during the War, our chemical industry produced also polythene—the finest insulator known—without which some of the most important applications of radio-location would have been impossible.

An insecticide (gammexane) probably more efficient than D.D.T., a range of selective weedkillers, linked with the discovery of the hormones produced in the growing tips of plants—which may well mean a revolution in agricultural methods—a synthetic adhesive, heat-, water- and acid-proof, giving unions stronger than those obtained by riveting or spot welding, are other achievements of our progressive and virile chemical industry.

The 'Mosquito', produced straight from the drawing board, largely by coach-building and furniture factories, and made operational in the record period of twenty-two months, could carry the same weight of bombs to Berlin as a 'Flying Fortress', with a crew of two instead of ten, and at 100 miles an hour faster. The British-made 'Lancaster' carried the biggest bomb-load and was the only aircraft capable of carrying the 10-ton bomb. Between 1939 and 1944 the Merlin engine was doubled in horse-power and performance, without any increase in weight, and we have recently read with pride what they think of it in the United States.

In the manufacture of scientific instruments, where during the First World War we found ourselves sadly behind, there is the same story of technical skill and successfully applied research. Our bomb-sights and predictors, containing incredibly delicate and complicated mechanism, were nevertheless robust enough to be carried in our bombers, and simple enough in operation to be used by technically unqualified personnel.

The measures to combat the magnetic mine—perhaps our greatest anxiety in the early months of the War—the prefabricated breakwaters and harbou known as "Gooseberry" and "Mulberry", and t submarine pipelines for carrying petrol to t Continent, are other outstanding examples of tec nical achievement.

The illustrations, which I could multiply ma times over in respect of a wide range of activitie show the high technical efficiency of British industri and their readiness to appreciate and develop ne ideas born in our research laboratories. I give the now merely in order to establish my contention th the prognosis in this matter of the application science in industry during the period of reconstructi is extremely favourable.

If that is accepted, let us look a little farther t see what is still needed in order to make the most our resources, actual and potential, and of our oppo tunities. This is the kernel of our problem, and I wi deal with it under the three heads of: (1) personne (2) finance and (3) organization.

Personnel. Sir Ernest Simon has directed attentio to the discrepancy between the numbers of scientifi ally trained personnel turned out by the universiti and other teaching establishments in the Unite States and Great Britain respectively. Allowing, of course one must, for the difference in total popul tion, we come very badly indeed out of the com parison. No doubt we make up to some extent i quality for lack of numbers; but the fact seems i disputable that the output has, in the past, bee far below what the real needs of the countr demand.

Clearly the deficiency, whatever it may be—an some further investigations seem called for under th head—cannot be made good all at once. The firs step must be to enlarge the capacity of our teachin institutions, to get more scientific men of high qualit back from war service to the teaching staffs of th universities, and then further to expand their number in the appropriate branches and perhaps to exten classroom and laboratory accommodation. This wi require some order of priority, and I have little doub that Mr. Morrison was right when he said re cently that the needs of industry must at first giv way to some extent before those of the universitie Then the necessary steps must be taken to increas the flow of students—not just any sort of student but students of the right type—with the best kin of general educational background. Some prop aganda will be needed here. I, personally, though it unfortunate that so little was made of the import ance of scientific and technical education during th passage of the Education Bill last year. I think great opportunity was lost; but no harm may resul in the long run if we do now what is urgently needed and that is to prepare the best possible estimate—quantitative and qualitative—of future requirement Universities, industrial firms and all other potentia employers, including the Government, should make and make known, their plans, indicating the type and numbers of trained men and women they require the terms they offer and the kind of organizatio they propose. Such information, properly collated will be an indispensable basis for the work of th committee on scientific priorities which Mr. Morriso recently announced in Parliament, and will als provide the necessary material for an approach t headmasters and, through them, to parents. As first step one cannot go wrong in urging that every thing possible should be done to hasten the release o trained scientific workers and of partly trained an trained students from the various forms of war rvice.

Finance. I come now to a matter which I would nk as high in importance as that of personnel— nance. Here I may modestly claim to have myself azed a trail. Broadly speaking, research and de- lopment must be financed in one or more of the llowing ways: by industrialists, either in their own boratories or through industrial research associa- ons, or through grants to universities and other ientific institutions; by universities and other ientific institutions out of their own resources; by overnment, through research institutions of its own, through grants to industrial research associations, individual workers or to universities.

While I was still Lord President, the basis of grants research associations was reviewed by the Advisory ouncil of the Department of Scientific and Industrial esearch, under Lord Riverdale, and now arrange- ents have been made which represent a very sub- antial improvement on the old. Whereas the epartment used to work on the principle that a overnment grant would be available only until the ssociation could be made self-supporting, the prin- iple of a permanent grant is now accepted, and the asis of calculation has been liberalized. This marks fundamental change in outlook. Government rants to universities are made through, and on the ecommendation of, the University Grants Com- ittee, which has been reconstituted to bring it into oser touch with the universities. About a year ago, met the Committee of Vice-Chancellors and fore- hadowed a substantially increased rate of grant hich has now been voted by Parliament for the urrent year. In addressing them, I referred, in articular, to the need for a revision of university alaries, and I made it clear that, for the first time his year and in future, capital expenditure would be aken into account in assessing grants. It is left to ach university to allocate its grant as it thinks fit, ubject, of course, to any general understanding etween that university and the Committee. Grants armarked for specific researches are made not by he Committee but by the Department of Scientific nd Industrial Research, with the approval of the reasury. The Department also administers a scheme f maintenance grants for postgraduate students to llow them to be trained in methods of research.

Expenditure by industrialists is assisted not by irect grant but by a system of tax relief. Up to his year, maintenance expenditure in connexion ith research was allowed as a deduction from earn- ngs, in accordance with the usual principle, but no llowance was made in respect of expenditure of a apital nature. Under my Budget proposals of last year, to which statutory effect has now been given, ll research expenditure in connexion with any par- icular industrial undertaking is allowed as a de- luction from earnings before assessment of tax. This pplies to all expenditure on buildings, plant and equipment, and represents a clear departure from the hitherto sacred principle that untaxed income must not be used to produce additions to capital ssets. The same principle is applied to contributions by industrial firms to research associations or universities for research. The value, and of course the cost o the taxpayer, of such relief can be gathered from the contributions of this character which have already been made. For example, I.C.I. have given eighty fellowships at universities, of an average of £600 a year each, for research in physics and chemistry, and sciences derived therefrom, including engineering and chemotherapy. There are no restrictions or conditions attached to these fellowships. The Shell Group has made a gift of £435,000 to the University of Cambridge for a Department and chair of Chemical Engineering, together with a yearly grant of £2,500 for scholarships, and Courtaulds have given £118,000 for a similar purpose to the Imperial College of Science and Technology. I do not doubt that, as time goes on, many other similar grants will be made, thus adding greatly to the funds available for fundamental research. Of the funds devoted by the Government to research in its own institutions, little more need be said except that experience goes to show that there are certain forms of fundamental research which it will probably be agreed can be only satisfactorily developed in this way. I mention, by way of illustration, the work to be carried on in the new Aeronautical Research Establishment at Luton, and the future of research into the uses of atomic energy.

There seems to be little doubt that the expenditure directly incurred by the Government on research will increase substantially as time goes on. I hope in the summary I have given I have succeeded in showing that, so far as financial aid is concerned, we now have a framework within which all that is required can be secured.

Organization. The efficient use of our resources, limited as they must be for a long time to come, demands the best possible organization. Without seeking to dogmatize in any way, I would suggest the following: (*a*) There should be recognized standards of remuneration. (*b*) Conditions of service should be such as to facilitate interchange between establishment and establishment, and between one type of service and another. A uniform pensions scheme, such as the Federated Universities Superannuation Scheme, should help to this end. (*c*) Free exchange of information and ideas should be encouraged. (*d*) Without encouraging teaching institutions to undertake agency or contract work, research in applied science in such institutions should not be discouraged. (*e*) Similarly, the advantage of allowing a certain amount of fundamental research in industrial research establishments should be recognized. It should be remembered that it is to research, so conducted, that the discovery of the gas-filled lamp, which has meant an enormous annual saving in consumption of electricity, is due. (*f*) To prevent wasteful overlapping, the various industrial associations should establish special committees to discuss long-term programmes of research with representatives of the universities and the Government research organizations. In this connexion the question as to what fundamental researches can most profitably be conducted in Government establishments, or centrally in selected institutions, should be considered.

These are only suggestions which I hope may be thought worthy of further consideration; but, before leaving this part of the subject, in which my aim has been to indicate a number of questions which I think bodies such as the Manchester Joint Research Council might usefully explore, particularly in their regional aspects, it is right that I should say a word about the question of organization, so far as the arrangements of the central Government are concerned. I would unhesitatingly reject the suggestion, much canvassed of late, that there should be a Minister of Science. If we believe, as we must, that science enters into nearly every branch of human activity, there can be scarcely a Minister or a Department that is not interested in some way in the applications of science, and to add a super-Minister with general responsibilities and executive functions in relation to science could only lead to confusion. But that does not mean that I should be content with things as they are. We now have, in the Lord President, a Minister who is directly responsible for the general, as distinct from the departmental, scientific activities of the Government—the Department of Scientific and Industrial Research, the Medical Research Council, and the Agricultural Research Council. If a similar Council were set up for the social sciences, he would no doubt take that under his wing also. He has, during the War, been the channel of communication between the Scientific Advisory Committee and the Cabinet. I should like to see three changes made. First, I would have the Lord President formally recognized as the Minister responsible for dealing, on behalf of the Cabinet, and subject, where necessary, to reference to the Cabinet, with all general scientific questions in which the Government is concerned, including problems of organization, arrangements for Commonwealth or international conferences, and so forth. Secondly, I would continue the Scientific Advisory Committee, which was a special war instrument, on a peace-time footing, with some extension of personnel, as the principal adviser of the Lord President and the Cabinet in scientific matters. Thirdly, I would create a special section of the Cabinet secretariat, under an officer of appropriate qualifications and seniority, to assist the Lord President in the discharge of his new responsibilities. I believe, under arrangements such as these, the organization of the central Government would be suitably geared into the general complex of scientific organizations throughout the country.

Now I propose to say something about the position of our investigations into the use of atomic energy, and particularly about the prospects of industrial use. We have here a case where, as the result of a quite prodigious concentration of effort, such as could only have come about under the spur of war, results have been achieved in a few years which, in ordinary circumstances, would have taken perhaps ten times as long, or even longer. The work that has been done, of which I have some detailed knowledge, points clearly enough to certain lines of development in the future. I say nothing about the military problem. So far as industrial applications are concerned, it is quite certain that nothing has been discovered to justify the expectation that the energy released by an atomic explosion could be used directly as a source of industrial power, as, for example, the explosion of gases is used in an internal combustion engine, or a gas turbine, or in certain forms of rocket. The only method which existing knowledge suggests as practicable depends upon the conversion into heat of the energy released by a controlled process of nuclear fission. There is no difficulty in realizing this experimentally. But at the very outset practical troubles begin to arise. The first problem is to get the heat in a convertible form. This means a high temperature and involves very efficient controls and special measures to prevent corrosion of the metallic components and the rapid disintegration of the whole system.

The other major problem arises in connexion with the intense and very dangerous radiation by which the nuclear reaction is attended. This means elaborate shielding devices and a complete system of remote control. It would be absurd to suppose that these and other difficulties will not be overcome time, and there is always the possibility of so fundamental new discovery completely changing t character of the problem ; but the best opinion I c offer—and it is not based on my own conclusion b on the conclusions of those on whose judgment can most confidently rely—is that it will be man years before nuclear energy comes on the market, f any but the most limited and specialized purpos in competition with existing sources of power.

Nevertheless, the ultimate possibilities are su that it is clearly incumbent upon us as a nation devote all the resources we can spare to furth researches in this field. There will, I imagine, I little doubt that the Government must, for the tin being at any rate, take a leading part in the organiz tion of such researches. Nevertheless, I must stre the fact that these recent discoveries open up a enormous new field of scientific work, and shou give tremendous impetus to research by physicist chemists and engineers. Indeed, the matter go much farther, for the devices that are employed t produce the new element plutonium provide a read means of procuring a vast range of new radioacti substances, including radioactive forms of commo elements used in medicine. For example, radi phosphorus, radio-iron, radio-sodium and many oth substances can now be administered with the norm substance in proportions too small to be harmfu and their radioactive properties can be used to determ ine the exact behaviour of the particular therapeuti or nutrient agent in the human or animal organism It does not require much knowledge, or much imag ination, to realize what a revolution this may brin into medical science. In plant and animal physiolog it may be equally important. There are also no available many alternatives to radium which ma be both much less expensive and more manageabl in radio-therapy. Thus, what may prove to be a uncovenanted benefit of inestimable value accrue to humanity as a by-product of the search for furthe means of destruction—proving again the truth of th saying that science often bestows her boons wher no one planned.

THE EDIBILITY OF BIRDS

By Dr. HUGH B. COTT

Department of Zoology, University of Cambridge

IN the autumn of 1941 I happened to be preparing some bird-skins at Beni Suef, Middle Egypt, when a casual observation led to what has proved a somewhat fruitful and little-explored line of inquiry. A palm dove (*Streptopelia senegalensis*) and a pied kingfisher (*Ceryle rudis*) had been skinned and the carcases thrown aside. Hornets were very plentiful in the garden where I was working and soon collected on the meat; but they were seen to concentrate their visits on one carcase, leaving the other almost neglected. Closer inspection showed that it was the dove that was receiving their attentions: with the kingfisher they would have little to do.

This apparent preference for one bird of the pair suggested further investigation, and it was decided to test the edibility of a wide range of birds, using *Vespa orientalis* as an indicator. Innumerable observations and experiments have hitherto been made n the palatability of various groups of animals—notably insects—with special reference to the theories of concealing and warning coloration and mimicry[1a]; but so far as I am aware, birds have remained largely neglected in this respect. The experimental method here adopted is an inversion of that so frequently used, in which birds have played the part of taster in investigations on the palatability of insects.

During the period 1941–44 many experiments were carried out, both in Egypt and the Lebanon, as a result of which it has been possible to assess the relative edibility of some forty species of birds in terms of hornet-preference. As the work developed, it became clear that the preferences of the insects were not dissimilar from those of other and quite unrelated meat-eaters such as the domestic cat and man. Details of this research will be published elsewhere: it is only possible here to refer briefly to some points of interest.

Among the birds tested were members of several Passerine families, including larks, wagtails, bulbuls, flycatchers, warblers, finches, buntings and swallows, together with birds of other orders including wryneck, hoopoe, buff-backed heron, white stork and little owl. One broad conclusion to be drawn from this work is that in the birds used there appears to be a relationship between edibility of the flesh and visibility of the plumage.

When arranged in order of preference, it is found that the species heading the list are those with the most effective concealing coloration, wryneck (*Jynx torquilla*) and crested lark (*Galerida cristata*) taking first and second place. Reading upwards from the bottom of the series we have the following: white-rumped black chat (*Oenanthe leucopyga*), pied kingfisher, mourning chat (*O. lugens*), masked shrike (*Lanius nubicus*), hoopoe (*Upupa epops*), hooded chat (*O. monacha*), golden oriole (*Oriolus oriolus*), red-backed shrike (*L. collurio*), lesser grey shrike (*L. minor*), European swallow (*Hirundo rustica*), common kingfisher (*Alcedo atthis*), red-rumped swallow (*H. daurica*)—all birds which in the field are highly conspicuous, the chats referred to being black-and-white deserticolous species.

Two striking exceptions to this general statement were provided by the buff-backed heron (*Ardeola ibis*) and white stork (*Ciconia ciconia*), both of which are extremely conspicuous and at the same time relatively palatable. It will be noted that both are large birds, which by reason of gregarious habits in the first case and powers of defence in the second are presumably not much subject to predacious attack in Nature.

This inverse relationship between edibility and visibility appears to occur in certain cases even within the limits of a family. For example, the finches and a bunting tested are found to stand in the following order of preference: greenfinch, house sparrow, Spanish sparrow, Cretzschmar's bunting, goldfinch, the last being rated least acceptable. Similarly, the blue-headed wagtail appears to be preferred to the white wagtail.

Experiments with the preferences of the cat for birds of various species have not yet reached a stage which would justify drawing any general conclusions; but it may be mentioned that in some instances the cat seems to be in close agreement with the hornet in his notion of what is fit to eat. For example, cats rate the pied kingfisher, hoopoe and a black-and-white chat (*O. finschii*) as relatively distasteful compared with sparrows, doves and other birds.

When we turn to the preferences of man, it becomes apparent that the birds—of many groups—which are most prized for the table are those which are specialists in cryptic camouflage; it is only necessary to mention a few: Passeres (skylark[2a], meadow lark[3]); Columbiformes (various fruit pigeons such as *Osmotreron pompadora*[4] and *Vinago delalandii*[5]); Charadriiformes (American golden plover[6] and grey plover[7], woodcock[8], common snipe[2b], stone curlew[9], bronze-wing courser[10a]); Gruiformes (bustards[2a,10b,11] and floricans[12,13a]); Galliformes (notably grouse and quail); Anseriformes (teal, mallard*, gadwall and others); Caprimulgiformes (European nightjar[16]).

Conversely, there is some evidence that numbers of highly conspicuous birds belonging to many different orders are definitely unfit for the table: sheld-duck[14], crocodile bird[15], magpie[16], and swallows being examples, though there are, of course, notable exceptions, such as the rook and starling, which make tolerable eating. Furthermore, here again within certain natural groups of birds the general correlation obtains. To take one example, among the Ralliformes, landrail[13b], clapper rail[17], and Carolina crake[18] are highly palatable and cryptic in coloration and habits; coot[19] and moorhen[18], though 'eatable', are scarcely accountable as table-birds and are among the most conspicuous members of the order.

Thus there would seem to be some evidence that the correlation above referred to is fairly general among birds as a class, and these facts would appear to bring birds into line with other groups of animals such as the Anura[1b] and Insecta[1a], in which the relationship between edibility and cryptic coloration on one hand and between certain classes of conspicuousness and unpalatability on the other, has been well established.

I am at present collecting further information on the above subject and would be glad to hear from members of expeditions, travellers, sportsmen and others who have tasted birds—of whatever kind—which are *not* usually considered as game. Such information is infrequently included in ornithological literature and would be welcomed as a contribution to the present investigation.

---

* Where the seasonal or sexual plumages differ, that of the female in breeding plumage is taken as the standard.

EXPERIMENTAL IMITATION OF TUMOUR CONDITIONS

By DR. P. T. THOMAS

John Innes Horticultural Institution, Merton, London

THE cancer investigator is primarily concerned with the nature and origin of uncontrolled growth in malignant tumours which depends on an aberration of normal cell division. The processes which underlie normal cell division and differentiation, however, are still far from being well understood. Cytology, so long as it remained a descriptive science, made little progress in this direction. But the change which occurred some fifteen years ago, when its methods became analytical and experimental, has by now made possible the interpretation of some growth processes in physico-chemical terms[1]—an advance which has in its turn stimulated a greater co-ordination among the different methods of approach to the cancer problem. Especially this advance has confirmed the remarkable uniformity of nuclear behaviour throughout living organisms. Experimental work on widely different organisms can therefore now be used to contribute to our understanding not only of normal but also of abnormal growth.

The condition of malignancy is accompanied by well-defined cytological changes, most of which have long been known[2,3,4]. The following are the most conspicuous: (1) 'hyperchromatism'—increase in size of chromosomes and a higher staining capacity; (2) enlarged nucleolus; (3) increased basophily of the cytoplasm; (4) increase in cell and nuclear size and a greater variability in both; (5) wide variation in chromosome number; (6) defect in the spindle at mitosis with its consequences.

Although different tumour types vary in detail, all malignant tissues and most malignant cells show one or more of these abnormalities which serve to distinguish them from the normal. Thus the difficulty of the cytologist has not been so much in distinguishing between normal and malignant cells but in deciding: (1) if there is any causal sequence among these various abnormalities; (2) if any of them can be regarded as a specific criterion of malignancy.

Failure to answer these questions has led to much confusion and differences in interpretation. The easiest way to find an answer seems to be to try to separate the particular abnormalities experimentally. We must try to induce them in non-malignant tissue in order to determine their immediate causes, from which it should be possible to establish the probable sequence of events in tumours.

A good deal of evidence is already available in support of the view that nucleic acid supply is the crucial factor in the causation of cancer. This view has developed largely from the work of Caspersson[5], Darlington[6], Claude[7] and others who have demonstrated the significance of nucleic acids and nucleoproteins in cellular activity.

We are concerned with two types of nucleic acids:

(1) *Ribose nucleic acid*, produced apparently by the heterochromatic regions of the chromosomes and found in the nucleolus and in the cytoplasm. This acid is closely associated with protein synthesis and especially with reproduction of self-perpetuating protein elements in the cytoplasm. It can be identified, with the help of a ribo-nuclease check, by staining with pyronin by Pappenheim's pyronin-methyl green technique.

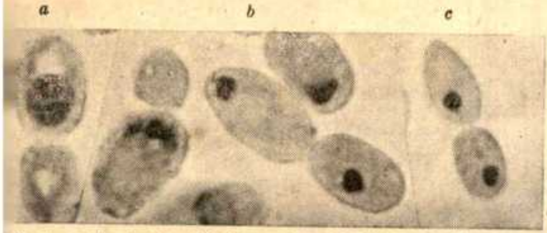
(2) *Desoxyribose nucleic acid* is produced during th prophase of mitosis, becomes attached to the chrom somes and is responsible for their reproduction. A the same time the nucleolus, with its store of ribo nucleic acid, dissolves and disappears. After th chromosomes have divided and reformed as daught nuclei they give up most of their charge of desox ribose nucleic acid, which is again reconstituted ribose nucleic acid in the developing nucleolu Desoxyribose nucleic acid gives the characterist aldehyde reaction with Schiff's reagent which is th basis of Feulgen's technique for chromosome stainin

The two nucleic acids are thus mutually (althoug not directly) convertible, and in normal tissue are s balanced that chromosome reproduction and cyt plasmic synthesis are in step. Caspersson conside that this balance is maintained by the regulatin action of heterochromatin[5], which under norm conditions allows the synthesis of the correct amoun of nucleic acid. Any increase in activity or in amoun of heterochromatin will, on this view, lead to excessiv nucleic acid synthesis and increase in the rate nuclear division.

Koller[8], from a cytological study of human tumour finds support for this view. Thus malignant cells hav a much enlarged nucleolus and a highly basophili cytoplasm because of the higher concentration of ribos nucleic acid. In the same way the 'hyperchromatism by which cytologists have described the larger an more deeply staining chromosomes is due to a heavie charge of desoxyribose nucleic acid. Confirmation o this interpretation has recently been obtained by L Cour[9], who found that in the unbalanced differentiation of cells in pernicious anæmia, nucleic aci supply in the red corpuscle precursors is increase and that in the white diminished.

We may now consider two experiments in which a least certain aspects of the primary change to malignancy is imitated. The first was with *Sorghu purpureo-sericeum*. Here the presence of supernumerary heterochromatic chromosomes is accompanied by a striking change in nuclear behaviour i the developing pollen[10]. Normally the first polle grain division which produces the vegetative an generative nucleus is followed after a week by th division of the generative nucleus to give two sperms But in pollen grains with extra chromosomes th vegetative nucleus immediately divides again an continues to divide until it has produced four or fiv generative nuclei. These divisions would presumably continue further but for the thick wall which confine the growth within the grain and makes it an 'encapsulated tumour'. Thus a nucleus which normally would not divide is induced to divide again and again owing to the action of extra heterochromatin introduced by a chromosome change.

The second experiment consists in the induction o giant mutant forms in yeast by the action of chemical carcinogens and camphor[11,12]. For example, Thaysen and Morris[12], by subjecting cultures of the non-sexual *Torulopsis utilis* to the action of camphor for several days, obtained a mutant in which the average cell volume was about double that of the normal. The generation-time for this new *major* strain ranged between 58 and 90 minutes as compared with 100–110 minutes for the standard strain. It was also found that "the percentage of nucleic acid extractable from a given weight of cells of the new strain was considerably higher than that obtained from the standard *Torulopsis utilis* strain". In agreement with this, the phosphorus content of the mutant strain, calculated



ig. 1. *a*, *Torulopsis utilis* VAR. *major* SHOWING LARGE FEULGEN-EGATIVE NUCLEOLUS AND CRESCENT-SHAPED FEULGEN-POSITIVE HROMOSOMES; *b*, VAR. *major* AND, *c*, NORMAL STRAIN SHOWING IFFERENCE IN CHROMOSOME SIZE. ALL PREPARATIONS STAINED WITH FEULGEN FOLLOWED BY ACETIC-LACMOID. (× 2000).

m the dry yeast, was 2·8 per cent as compared th 1·8 per cent for the original strain. Through e kind co-operation of Dr. Thaysen and his col- gue, I was able to study the two strains cytologic- y. I found that the nucleolus in the *major* strain s more than four times the volume of that in the ndard strain. Moreover, as can be seen in Fig. 1, e two Feulgen-positive bodies, which can be pro- rly regarded as chromosomes[13], are also greater in e. They presumably have an increased nucleic acid arge. Further, in a culture of the normal strain ich had been under the influence of camphor for o days, the mutant forms could be readily identified their staining. They showed increased basophilic action with Pappenheim's pyronin methyl green lution. They had a higher concentration of ribose cleic acid.

Thus in four respects, rapidity of division, increase size of nucleolus, and concentration of nucleic ids of both kinds, the mutant yeast cell exactly rees with a cancer cell. The change produced by mphor, as Thaysen remarks, is "deep-seated" or netic since the mutant form is stable and has not verted to the normal after continued subculturing. e action of camphor on yeast, therefore, has been to induce a specific effect on growth, by increasing nucleic acid metabolism. But here the change, although genetic, is probably not due to change in the chromosomes but rather to one in cytoplasmic determinants. The change is analogous to that of carcinogens in causing cancer in animals.

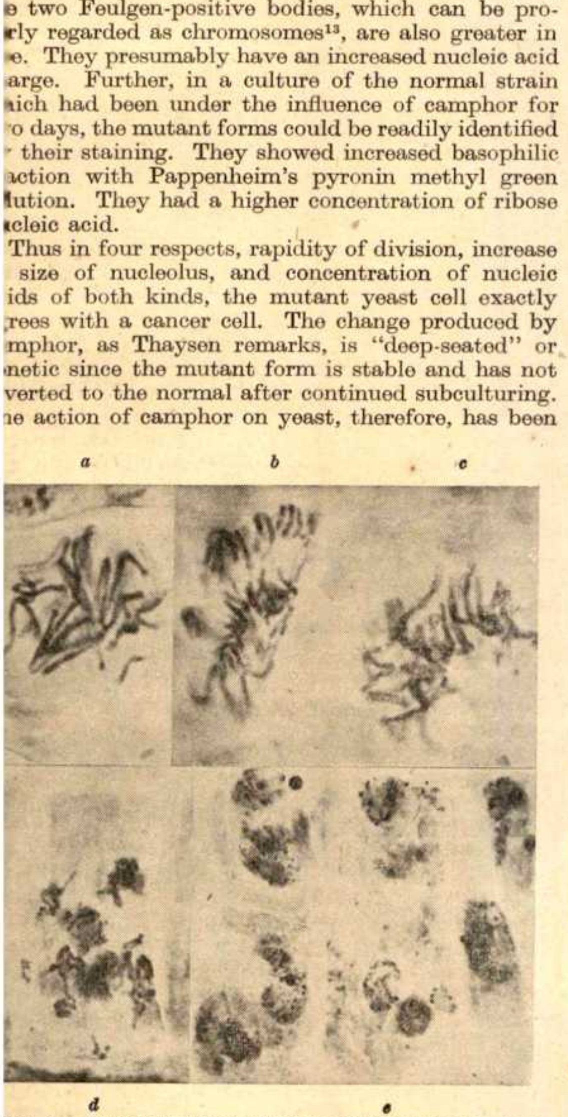


Fig. 2. ACTION OF LACTIC ACID ON ROOT-TIP TISSUE IN RYE (18 HR. TREATMENT WITH 250 P.P.M. *p*H 5·66. 28° C.). MULTIPOLAR SPINDLE AT EARLY ANAPHASE, *a*; LATE ANAPHASE, *b*; METAPHASE, *c*; TELOPHASE, *d*; WITH CONSEQUENT MULTINUCLEATE CELLS AS AT *e*. (× *c*. 1000).

Perhaps the most striking cytological abnormalities in tumours are those due to defect in the spindle at mitosis. In fact Boveri[14] originally thought that the multipolar spindle was a primary cause of tumour formation; but we now know that initially cell division is by normal mitosis and these abnormalities are absent or very rare in many types of tumours. They therefore seem to be secondary.

The spindle can be upset in normal tissue by a number of physical and chemical agents, producing effects which imitate the behaviour in tumours. The more effective agents, such as colchicine, cause complete suppression of the spindle, apparently by preventing the orientation of its long-chain molecules. The less-effective agents induce a multipolar spindle by preventing the co-ordination of partially orientated spindle elements. Complete suppression of the spindle leads to polyploidy, while partial suppression results in hypo-diploid nuclei and multinucleate cells. Both these conditions occur in tumours with the expected results. The latter is the commoner and is probably the main cause of cell degeneration.

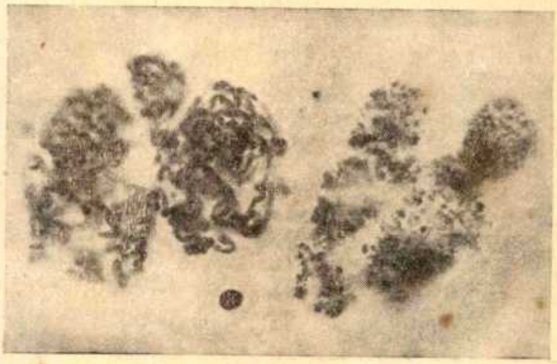

Fig. 3. AFTER 24 HR., SHOWING IRREGULARLY SHAPED POLYPLOID NUCLEI AT RESTING STAGE AND AT PROPHASE. THIS TYPE OF NUCLEUS IS OFTEN FOUND IN TUMOURS (*cf.* REF. 4, P. 257). IT RESULTS FROM A MULTIPOLAR SPINDLE. (× *c*. 2000.)

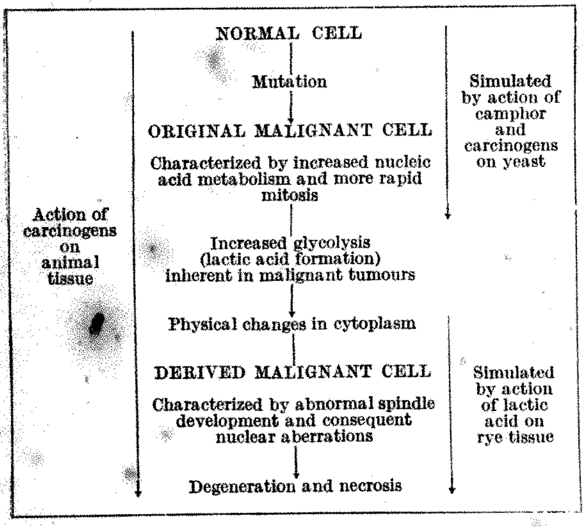
One of the less effective agents is lactic acid. Its action can be shown readily on root-tip tissue in rye. The abnormalities produced closely resemble those in malignant tumours (Figs. 2 and 3). The precise mode of action of lactic acid on the spindle will be discussed elsewhere. The action seems to be the same as that which Heilbrunn[15] terms "reversible coagulation of the cytoplasm" observed by him when studying the action of fat solvents and heat. The term "thixotropic setting" which Seifriz[16] uses for the action of anæsthetics in producing a reversible gelation of the cytoplasm probably refers also to the same physical change.

Now the accumulation of lactic acid, due mainly to aerobic glycolysis, is regarded as "the outstanding metabolic characteristic" of tumour tissue[17]. Hochwald[18] and Reiss[19] had already concluded that lactic acid was the cause of the central necrosis in tumours. More recently Guyer and Claus[20], from viscosity measurements, suggested that this acid might be the agent which induces the mitotic abnormalities by causing partial coagulation of the cytoplasmic proteins. We may therefore suppose from these different kinds of evidence that lactic acid is the immediate cause of spindle defects in tumours. The question as to whether the formation of lactic acid in the tumours is itself secondary and a consequence of excessive growth activity, or whether it is bound up with the primary change in nucleic acid metabolism, does not now need to concern us.

To summarize, we may arrange, as in the accompanying table, the probable sequence of events in tumour development.



NORMAL CELL
Mutation
ORIGINAL MALIGNANT CELL
Characterized by increased nucleic acid metabolism and more rapid mitosis
Increased glycolysis (lactic acid formation) inherent in malignant tumours
Physical changes in cytoplasm
DERIVED MALIGNANT CELL
Characterized by abnormal spindle development and consequent nuclear aberrations
Degeneration and necrosis
Action of carcinogens on animal tissue
Simulated by action of camphor and carcinogens on yeast
Simulated by action of lactic acid on rye tissue

The change from a normal to a malignant cell is of the nature of a mutation, but until recently we had few ideas as to how it might be brought about. We have seen that a change in the amount of heterochromatin may be one way and we also know that mutation in a single nuclear gene may induce polymitosis[21]. We now have the further possibility of an effect through mutation in cytoplasmic elements. In this there is a remarkable similarity of views between two workers engaged in entirely different fields of research. Darlington[22], basing his arguments primarily on cytogenetic grounds, considers that there are genetically important elements in the cytoplasm which are self-perpetuating. These he calls plasmagenes. They differ from viruses in their adaptation to the 'host' and in their interaction with the cell nucleus. Both plasmagenes and viruses depend on chemical equilibrium for their continuance, so that a mutation in them can alter not only their equilibrium but also their interaction with the cell nucleus. Potter[23], as an enzymologist, considers that cancer is caused by the introduction of "an abnormal protein" which he calls a "cancer virus" and which he assumes "to arise spontaneously in certain cases, to be formed by the action of carcinogenic agents in other cases and to be introduced into the cell in the case of tumours known to be of virus origin". This 'cancer virus' is assumed to be almost identical with an enzyme *X* which he believes is a complex of respiratory enzymes of the nature of a ribonucleoprotein. A change in equilibrium is brought about by competition between these two for the same 'building blocks', and when the ratio $\frac{\text{cancer virus}}{\text{enzyme } X}$ reaches a certain value the cell becomes malignant. The change is thought to be irreversible because the 'cancer virus' competes more successfully than enzyme *X* for the 'building blocks'. The reaction analogous to what Darlington calls 'suppressivene as between plasmagenes.

These experiments and theories seem to show th a common basis has been reached for the study the cancer problem. They seem to show also th the elements of the problem can be pulled apa robbed of their complexity and subjected to prof able experimental tests that will now have a meanin

I am much indebted to Mr. S. H. Revell for tec nical assistance with some of the experiments d cussed in this article.

OBITUARIES

Prof. C. E. Spearman, F.R.S.

Charles E. Spearman was born in London September 10, 1863. He came of a Northumberla family, the more prominent members of which ha been either Army officers or mining engineers. Wi one or other of these possible professions in view, gave himself assiduously in his early youth to t study of applied mathematics. Eventually he enter the Army, and served in the Burmese War. Duri the Boer War he was deputy assistant adjutan general in Guernsey; and in this way becan interested in problems of personnel. He resigned h commission in order to study experimental psycholog at Leipzig, at Göttingen, and at Würzburg.

Spearman's interests first centred on the proble of determining sensory thresholds. Here his math matical knowledge enabled him to suggest sever improvements in the psycho-physical methods Wundt and Muller. But, coming as he did with mature experience of practical affairs, he quick decided that the experimental psychology of tho days was engrossed too exclusively with questio far removed from those of ordinary human life. H early aim, therefore, was, in his own phrase, " connect the psychics of the laboratory with those of real life".

The idea of using sensory thresholds to measure general ability or intelligence he took from Galton. In the United States, one of Galton's own pupils, J. McKeen Cattell, had applied laboratory tests to students, and, on assessing the results by Galton's method of correlation, had been surprised to find that the agreement of the various modes of assessment was extremely low. Cattell, Thorndike and others were consequently led to the conclusion that there was no general faculty of intelligence, as Galton had assumed, and that the mind was a "host of particular abilities". This negative result Spearman believed to be erroneous. Adapting a more elaborate statistical procedure from Karl Pearson and Yule, he endeavoured to eliminate the irrelevant factors which appeared to be obscuring the underlying correlations, and then found an almost perfect agreement between the various tests and assessments. These results he published in one of his earliest and most important articles in 1904—"On General Intelligence Objectively Determined and Measured". In this research he believed he had demonstrated "the profoundly important conclusion that there exists something which we may provisionally term general sensory discrimination" ; and this he identified with "general ability" in Galton's sense. Few papers in psychology have given rise to such productive controversies and to so long a list of suggestive investigations.

In 1907 Spearman returned to England. At that time McDougall was interested in Galton's scheme for an anthropometric survey which should include intelligence tests. In France, Binet had produced his scale of tests ; and at University College, London, Karl Pearson had already been working with correlational methods applied to teachers' assessments of their pupils' mental characteristics. On McDougall's recommendation, Spearman was appointed reader in experimental psychology at the same College, and four years later became Grote professor of mind and logic. During the next twenty years, he and his research students were systematically engaged on demonstrating the supreme importance of a general intellectual factor, which he himself preferred to call, not intelligence, but *g*.

At first Spearman relied mainly on sensory tests of a laboratory type—the æsthesiometer, Galton's cartridge weights, and a dichord of his own invention for testing discrimination of pitch. Other workers in Great Britain, however, showed that better results might be secured by using tests of more complex abilities, particularly those involving the perception or use of logical relations, such as could be given without apparatus to large groups of children in school. These suggestions Spearman readily incorporated. His main interest, however, lay rather in the theoretical study of the mind in general than in educational or other practical applications.

His later work with tests of this new type led him to formulate his "fundamental noegenetic principles". According to this doctrine all intellectual processes were to be conceived as depending essentially upon the "education of relations and correlates". His first book, on "The Nature of Intelligence and the Principles of Cognition", gave a systematic picture of the workings of the human mind based on this hypothesis. It was quickly followed by a second volume on "The Abilities of Man", which gave the final statement of his 'two-factor theory'—the theory that all mental processes are pervaded by a single central function, combined with a second highly specific factor peculiar to each test or trait.

Later, in a smaller work on "The Creative Mind", Spearman endeavoured to show how his fundamental noegenetic laws could be applied to other intellectual fields. His last work, "Psychology Down the Ages", was a historical study in two volumes of the evolution of the chief doctrines of psychology, with the intention of showing how nearly all the more acceptable formulations were dim foreshadowings of his noegenetic laws.

In 1931, on his retirement, Spearman was made emeritus professor in the University of London. He had already been elected a fellow of the Royal Society, and been honoured by numerous scientific bodies in Germany, France, the United States and Czechoslovakia. All who worked with him, or discussed with him their common problems, will testify to his remarkable gift for inspiring enthusiasm both in his own colleagues and pupils and in those who were drawn to criticize his views. Few have possessed his power of co-ordinating and concentrating the interests of numerous research workers on a single fertile scheme.

C. BURT.

Dr. Frank Chapman

THE death has been announced of Dr. Frank Chapman, who for many years was head of the bird departments of the American Museum of Natural History, until his retirement in 1942.

Dr. Chapman was born at Englewood, New Jersey, on June 12, 1864, and on leaving school entered a New York bank. So keen on birds was young Chapman that he used to get up at daybreak, hunt birds on the way to the station, where he would arrive at 7.30, change into his city clothes and catch the 7.39 to town. All his spare time was devoted to collecting and studying birds, and after six years in the bank he decided that was not the life he could live. In 1886 he left the bank and two years later was appointed assistant to Dr. J. A. Allen, curator of mammals and birds in the American Museum of Natural History. This was the beginning of his long connexion with the Museum and the great bird collection which was so wonderfully developed under his charge. When Chapman joined the Museum the study collection consisted of only 300 skins ! Under the joint care of Allen and Chapman the collection grew apace, and the latter made many expeditions to different parts of the States and the West Indies to secure further material.

Early in his career Chapman became interested in the life zones of the Andes, and thereafter most of his work was devoted to studying the birds of the Andes in Venezuela, Colombia, Chile and Peru. He published several monographs dealing with the subject and was the recognized authority on the birds of these regions. As Chapman himself wrote, he was more interested in watching live birds in the field than in collecting or studying skins, and after the First World War he settled on an ideal spot for the purpose. This was Barro Colorado Island in the Panama Canal zone, and there he built a house, called Fuertes House, after his friend the American bird artist. Here he could study and photograph wild life to his heart's content. Among the trees toucans, guans, parrots and woodhewers abounded, and down below were ocelots, peccaries and other interesting mammals. The joys of the place and what can be seen are described in "My Tropic Air Castle".

The love of birds brought Theodore Roosevelt and Chapman together, and through Roosevelt he was invited by Lord Grey to the British Embassy to talk birds. Later, during visits to Great Britain, he was taken by Lord Grey to see birds in the New Forest and along the banks of the Itchin, and a few years after he paid a visit to Fallodon which is vividly described in the "Autobiography of a Bird Lover".

Chapman was an ardent protectionist and for many years edited *Bird Lore*, the magazine of the Audubon Societies. In 1893 he published a useful "Handbook of Birds of Eastern North America", a revised edition of which appeared in 1912.

To Chapman the American Museum owes the development of the habitat groups for which that Museum is so famous.

In 1898 Chapman married Miss Embury, and the marriage was an ideally happy one, his wife developing as keen an interest in birds as her husband and often accompanying him in the field. N. B. KINNEAR.

Dr. H. E. Durham

BY the death at Cambridge, on October 5, of Dr. Herbert Edward Durham both bacteriology and botany lose a distinguished discoverer. Durham was born in London in 1866. He was the son of A. E. Durham, senior surgeon to Guy's Hospital and a grandson of William Ellis, the economist. Educated at University College School and King's College, Cambridge, Durham took first class honours in Parts I and II of the Natural Sciences Tripos at Cambridge in 1890, his medical qualification in 1892 and his F.R.C.S. in 1894. In 1894 he was appointed to a Gull Research Studentship and went to Vienna to work in Gruber's hygiene laboratory. There he and Gruber first directed attention in January 1896 to the diagnostic value of the agglutination of pathogenic organisms by the sera of animals immunized against them. Later in 1896 this test was applied by Widal for the diagnosis of typhoid fever. The reaction was known for a time as the Gruber-Durham reaction and later as the Widal reaction.

In 1896 Durham was appointed a member of a Royal Society committee upon diseases transmitted by tsetse flies. In 1897, while holding a Grocers' Scholarship and working at Cambridge, Durham described the Durham tube, a small inverted test-tube placed in bacteriological media for the collection of the gas produced by fermentative organisms. In 1900 he headed the expedition sent by the Liverpool School of Tropical Medicine to Brazil to study yellow fever. Durham contracted the disease, but lived to lead, during 1901–3, the expedition sent by the London School of Tropical Medicine to Christmas Island and Malaya for the study of beriberi. From Malaya, Durham brought home samples of *Derris elliptica* and appears to have been the first to recognize the insecticidal properties of this plant.

In 1905 Durham was appointed supervisor of the laboratories of Messrs. H. P. Bulmer and Co., of Hereford, where he worked for thirty years upon problems of fermentation and apple culture in relation to cider production. In 1909 he took his Sc.D., Cambridge, and in 1935 retired to Cambridge, where he cultivated, in his garden there, many culinary plants and herbs which are rare in Great Britain. Many of these he had himself introduced, and several Cambridge gardens still cherish those which he gave to their owners.

A retiring man who could be a charming and humorous companion, Durham acquired a wide culture and was always ready to give of his rich store of experience to his many correspondents and friends. He sent many valuable contributions to the "Dictionary of Gastronomy". Responsible for much original work, and also for much stimulation of others, he scattered his knowledge in private communications and did not always obtain full credit for his discoveries. Not least among his later activities were his hobbies of photography and lathe-work. While his bacteriological work is well known, his contributions to botany, and especially perhaps to apple culture and problems of fermentation, merit wider recognition. The sympathy of everyone will go out to Mrs. Durham, who survives him, and to his brother, Colonel F. R. Durham, secretary of the Royal Horticultural Society. G. LAPAGE.

Prof. C. E. Wright

THE death of Prof. C. E. Wright, professor of gunnery and mathematics at the Military College of Science, Woolwich, occurred on October 30, 1945.

Charles Edward Wright was born on January 31, 1886. He studied mathematics at King's College, London, between 1903 and 1906, where he was awarded the Clothworkers' and Sambrooke Exhibitions and a Drew Gold Medal. After graduating he was appointed tutor at University Correspondence College, Cambridge. During the War of 1914–18 he served with the Royal Engineers and was, for a short time, at the Research Department, Woolwich. He obtained the degree of M.Sc. by examination at Queen Mary College, London, in 1921.

In 1919, Wright took up the appointment of senior lecturer at the Military College of Science, Woolwich, where he spent the greater part of his career and where he was appointed professor shortly after the retirement of Prof. H. C. Plummer in 1940. Wright was wholeheartedly devoted to the instruction of army officers to fit them for technical staff appointments. The many students who have worked under him have proved their value during the recent War, where their services have proved indispensable in the development and production of weapons to meet the needs of the soldier in the field. Apart from his professional duties, Wright was actively engaged in voluntary war work, but alas, his zeal was greater than his strength.

He was an able mathematician and, in addition to his instructional duties and the preparation of Service text-books on ballistics, he found time to write several papers and notes published in the *Philosophical Magazine* and educational journals. The elegance exhibited in some of his mathematical work is most attractive. He was of a cheerful disposition and was popular with students and staff alike. C. J. TRANTER.

WE regret to announce the following deaths:

Dr. E. F. Armstrong, F.R.S., on December 14, aged sixty-seven.

Mr. A. Lucas, O.B.E., sometime chemist to the Egyptian Department of Antiquities, on December 9, aged seventy-six.

Mr. F. Milsom, for many years the official referee for Hepatics for the British Bryological Society, on December 5.

NEWS and VIEWS

Geological Survey (Scottish Office)
Dr. Murray Macgregor

The retirement of Dr. Murray Macgregor during the past autumn brings to a close a long and eventful term of office in charge of the Geological Survey in Scotland and north-east England. On joining the staff in 1909, Dr. Macgregor was stationed at Edinburgh, and in 1921 succeeded the late Mr. L. W. Hinxman as district geologist for the Central Coalfield and Northern Highlands; and in 1925 he was appointed assistant director for Scotland. Dr. Macgregor has rendered signal service both in organizing and personally conducting geological investigations for industrial developments in Scotland. He will, however, be remembered especially for the close contact which he maintained with those engaged in the coal-mining industry. In addition to his many contributions to the economic geology of the coalfields in Survey memoirs he has written a comprehensive account of Scottish Carboniferous stratigraphy, which was published by the Geological Society of Glasgow in 1930. During the past twenty years a large programme of normal survey work was carried out under Dr. Macgregor's guidance. The first revision of the Scottish and Northumberland Coalfields was completed, as well as a second revision of a large part of the Central and Lothians Coalfields and the oil-shale field of the Lothians. Up to the outbreak of war in 1939, striking progress had also been made with the primary survey in several areas in the Highlands and Islands. During the war years the activities of Dr. Macgregor and his staff were concentrated upon economic aspects of geology, related to the War itself and to reconstruction. A number of special investigations were carried out at the request of several ministries and to meet various industrial needs. Among these may be mentioned a detailed examination of Scottish limestones, mainly for agricultural purposes, a search for feldspar, silica-rock, mica and iron ore, surveys of underground water resources and of areas for open-cast coal production, and an investigation of building materials, including slates, brick-clays and granite.

In addition to his Survey duties, Dr. Macgregor has contributed largely to scientific journals and to the work of scientific societies. He has served as president of the Edinburgh Geological Society and the Geological Society of Glasgow, as editor of the *Transactions* of the latter Society over a long period of years, and as member of council of the Royal Society of Edinburgh. He is a vice-president of the Geological Society of London. In 1941 he was awarded the Murchison Medal by the Geological Society of London, and in 1944 the Clough Medal by the Edinburgh Geological Society.

Mr. T. H. Whitehead

Dr. Murray Macgregor is succeeded at Edinburgh by Mr. T. H. Whitehead, who joined the Geological Survey in 1914. During the First World War he served in the Suffolk Regiment, reaching the rank of captain, was severely wounded and afterwards was appointed to the Intelligence Staff. Among his important published work is the Geological Survey memoir on the South Staffordshire Coalfield, in which he collaborated with T. Eastwood, now assistant director in England; other memoirs of which he is a principal author are those on Coventry, Birmingham, Stafford, Wolverhampton and Shrewsbury. In 1933 he was transferred to the Manchester branch office, and from 1935 until it was closed in 1938 he was in charge of that at York. During the War he has been the district geologist responsible for urgent revision work on the coal and other resources of the Midlands, and for the six-inch survey, now completed, of all the Jurassic and Cretaceous iron-ores south of the Humber. Whitehead's judicial mind and terse clarity in argument are acknowledged and admired by his colleagues of the Survey and Museum, whom he has served well both as counsellor and advocate, and by his fellow-members of the Council of the Geological Society. These qualities, coupled with his extensive and intimate knowledge of British geology and its economic applications, make him admirably suited for his new post.

University of London, Institute of Education :
Prof. Karl Mannheim

Dr. Karl Mannheim has been appointed to the chair of education in the University of London, in succession to Sir Fred Clarke, who retired at the end of the last academic year. The appointment dates from October 1, 1945, and is tenable at the University Institute of Education. Mannheim's appointment may be regarded as both daringly original and a sign of the times. A Hungarian by birth, he gained his doctorate in philosophy at the University of Budapest, and was becoming known as a sociologist of repute while teaching in Germany before 1933. The events of that year brought him to Britain, and to a lectureship in sociology in the London School of Economics. In 1940 his impressive study of "Man and Society in an Age of Reconstruction" established him in the front rank of sociologists, and the collection of essays he published in 1943 under the title of "Diagnosis of our Time" enhanced an already considerable reputation.

Mannheim has always shown himself peculiarly sensitive in his sociological studies to the importance of education, and since 1941 has been attached to the staff of the London University Institute of Education, but can scarcely be regarded as possessing the normal professional qualifications for a professorship in the subject. Paradoxical as it may seem, this is probably why he has been appointed. The Institute, under the leadership of Sir Fred Clarke, has in recent years been laying increasing emphasis on the social aspect of public education, and insisting that the philosophy of education must be worked out on a sociological basis. No one is better fitted to undertake this task than Mannheim.

Benjamin Rush (1745-1813)

Born on Christmas Eve two hundred years ago, Benjamin Rush remains one of the most versatile and colourful personalities in American history, and the greatest physician America has produced. One of the signatories of the Declaration of Independence, treasurer of the U.S. Mint, founder of the American Anti-Slavery Society, advocate of prison reforms, it is upon his reputation as a physician that his immortality rests. His account of the yellow fever epidemic which swept Philadelphia in 1793 won him international fame, while the singular courage and the untiring devotion to duty which he displayed in attending to its victims raised him in popular imagination to the stature of a hero. His descriptions of cholera infantum and of focal sepsis—he was one of the first to recognize the relationship between infected teeth and arthritis—have become medical classics. Though many of his theories are to-day of historic interest and many of his therapeutic measures have been discarded, his title 'father of American psychiatry' is justified, for his "Medical Inquiries and Observations upon the Diseases of the Mind", published the year before his death, was the first American text-book on psychiatry, and he was a pioneer in the humanitarian treatment of the insane and an early advocate of occupational therapy in asylums. A magnetic teacher, an elegant speaker and a felicitous writer, Benjamin Rush was a pronounced individualist, who made enemies as well as friends. He was one of the greatest 'bleeders' in the annals of medicine.

The Good and the Clever

It was a happy inspiration which caused the Master of Balliol to base his Memorial Lecture at Girton College, Cambridge, upon the verses in which Miss Wordsworth referred to the possible antithesis between goodness and cleverness, when "the good are so harsh to the clever", and "the clever so rude to the good". He set out to show that nothing will make sense of the distinction, except to acknowledge that goodness is in its own way as rational as cleverness. "Let us begin with the Greeks," said he to his hearers, and then, as became his learning and his office, he took them through a fascinating journey from the Greeks on to the Renaissance, and thence to Rousseau, Kant and Bentham. Naturally, those of his hearers who had studied philosophy to some purpose must have got most out of this part of his discourse; but none of them could have missed the heart of his theme, which was that "the really good man may not be learned or intellectual, but though he need not be clever he is not stupid. He has the imaginative power of putting himself in other people's places, and of going right past differences of rank and wealth and ability and all else, and getting to the essential human being". One remark will be of special interest to readers of this journal, devoted to science in its broadest interpretation. "Psychological classifications, case papers, and all the elaboration of card indices does help one to deal more effectively with people, but the most elaborate and scientific analysis misses out the authentic individual, just exactly what goodness should have the power of apprehending. If we only deal with people as specimens of this or that, sorted out in the most elaborate of ways . . . can we retain that reverence for the human personality as we meet it in ordinary men and women which is essential to any true service. . . . Good and noble work has been done in that way, but not the best." It must have been a salutary experience for members of the particular audience addressed to be so effectively reminded that good men and women are sometimes also exceedingly wise, and that clever men and women can sometimes also be exceedingly unwise.

"Faraday's Encyclopedia of Hydrogen Compounds"

The scope of this important new aid to using chemical literature has already been explained in *Nature* (April 21, p. 467). Dr. Faraday and his publishers are to be congratulated on the fulfilment of their promise to keep it up to date by producing the first instalment of supplementary pages. This is no mean achievement in relation to the well-known difficulties of the moment with which printers and publishers are faced. The single sheets of the first replacement addition issue (C_1—C_5) cover the year 1944 and bring the book up to January 1, 1945 (Chemindex, Ltd., Manchester 2. Pp. 64. 15*s*.). We know of no other book of reference in science which is in this happy position. On trial, it was found that the necessary work of changing the sheets and adding new ones took less than half an hour; the instructions given are so precise that any intelligent person can follow them. The new matter fits easily into the system and only three correction sheets were required, which is a testimony to the care taken in the original preparation. A leaflet enclosed with the sheets promises a second volume dealing with C_6 and C_7 shortly, while others are ready for the printer: we believe the practising organic chemist will be eager for these. It is of interest to note the degree to which the various abstract journals cover the published literature. A spot test of a random sample has shown that *British Chemical Abstracts* covered 27 per cent, *American Chemical Abstracts* 57 per cent and *Chemisches Zentralblatt* 70 per cent. On the basis of these figures, there seems room for improvement in Great Britain.

Research Corporation Grants for Research

Some 2,500,000 dollars is being offered in grants to educational institutions by the Research Corporation of New York, a non-profit organization devoted to advancing research and technology by the use of revenues from inventions assigned to it by public-spirited inventors. Preference in making these grants will be given, other factors being equal, to smaller institutions and those of more limited financial resources for research. The five-year programme announced by Dr. Joseph W. Barker, acting president, who is dean of engineering at Columbia University and until recently was a special assistant to the Secretary of the U.S. Navy, provides for one to two hundred grants of 2,500–5,000 dollars a year to enable young men of science, engaged for the most part in war research in uniform or as civilians, to undertake at universities and colleges research of peacetime importance in pure science, especially chemistry, physics, mathematics and engineering. The first grants will be made shortly by a special committee of eminent men of science from industrial and university laboratories. Grants will be made to the institutions at which successful candidates will work and teach. The funds allotted will be available for the purchase of needed equipment and for the employment of assistants either as fellows or otherwise. Awards will be based primarily upon the demonstrated ability of the men who will conduct the researches and contribute to the teaching programme of the school. The grants are made possible by the fact that during the war years research programmes that would be normally supported by Research Corporation grants have been laid aside in order to free men and facilities for war research. The Research Corporation was begun in 1912 with the gift, through Dr. F. G. Cottrell, of patent rights on electrical precipitation, which is used for removing dust, fume and mists from industrial gases and from the atmosphere. From revenues derived from these and other patents it has made grants of 1,279,637 dollars in past years to fifty-two institutions. In recent years the Corporation has served universities by administering inventions that may in their laboratories. Correspondence in con- on with the grants should be sent to Dr. Robert R. ams, Research Corporation, 405 Lexington ue, New York 17, N.Y.

ilization of Syringes

E difficulty of sterilizing syringes satisfactorily been the subject of much recent research. A ing article in the *Lancet* (111, July 28, 1945) isses this problem, the importance of which is hasized by the publication, in the same issue 106), by E. M. Darmady and C. Hardwick, of ccount of hepatitis in ten subjects which followed administration, by means of syringes, of pentothal penicillin. These authors discuss the difficulties roving the possibility of the transmission by nges of the small amounts of blood containing cterogenic principle which are required to pro- hepatitis. The icterogenic principle involved hese authors say, so heat-resistant that ordinary hods of sterilization of syringes do not destroy it. longed heat is necessary for this. The use of lles alone for the withdrawal of blood for lab- ory purposes would also prevent the contamina- of whole syringes. The discussion of the same lem in a memorandum issued by medical officers he Ministry of Health, recorded in the same issue he *Lancet* (p. 116), comes to the conclusion that sion of existing injection techniques is required, that hepatitis following the injection of arsphen- ne, gold and other substances is an expression of ologous serum jaundice communicated by traces blood transferred from subject to subject on nges and needles. It is, of course, easy to over- mate the dangers which may result from existing hods of sterilization of syringes. Millions of ctions must be done every year without untoward lts. But the evidence recorded here emphasizes importance of the report of the committee ointed by the Medical Research Council (M.R.C. r Mem. No. 15, H.M. Stationery Office, 1945, 4*d.*) onsider the sterilization of syringes. This report ld interest the experimental worker as well as the ical man, for, in certain kinds of experimental k, the results may be seriously affected by in- quate attention to the cleaning of syringes and lles.

icity of D.D.T. to the Housefly

URING the War the importance of the compound lly referred to as D.D.T. as an insecticide has demonstrated. In the *Bulletin of Entomological arch* (**36**, Pt. 2; Sept. 1945), E. A. Parkin and A. Green, of the Pest Infestation Laboratory at gh, describe experiments in testing the efficacy controlling the housefly (*Musca domestica*) by ns of D.D.T. They found that when applied as pray containing 0·1 per cent w./v. or more of .T. in kerosene it is very toxic to the insect in stion. At 1 per cent strength D.D.T. gives an ctive spray for practical use but at lower con- rations its action is too slow. Its advantages fly spray are that it can be prepared synthetically; almost odourless; it will not stain fabrics, etc.; ppears to have no marked irritant effect upon operators up to 2 per cent strength; it is ex- nely lethal to flies both in solution and in the d form after deposition on walls, etc., from volatile ents. Its main disadvantage is its slow rate of on on flies unless used at a concentration of at least 1 per cent w./v.; but, even at this strength, affected flies produce an unwelcome buzzing, for at least an hour prior to the wing muscles becoming paralysed. The slow action of this compound can be overcome by the admixture with D.D.T. of a small amount of pyrethrins which has a very rapid paralytic effect. It would appear that the two constituents act independently, the rapid effect of the pyrethrins keeping the flies immobile until the slow lethal action of the D.D.T. has had time to come into effect.

British Rheologists' Club

THE fifth annual general meeting of the British Rheologists' Club was held at the Engineers' Club, Manchester, on October 5. Dr. G. W. Scott Blair, the retiring honorary secretary, reported on the activity of the Club during the year 1944–45, and stated that membership had reached the three hundred mark. The Club had held four general meetings, and two bulletins of information, abstracts, etc., had been issued. Close contact had been maintained with the Society of Rheology (United States), and contacts had begun with rheologists in the U.S.S.R., France and other countries. The Proceedings of the Oxford Conference were nearly ready and would be published in book form. Prof. E. N. da C. Andrade was re-elected president for the ensuing year. Dr. E. W. J. Mardles of the Royal Aircraft Establishment, Farnborough, Hants, was elected secretary; a vote of thanks was moved from the chair to Dr. Scott Blair, who had been secretary of the Club since its inception in 1940. The meeting was followed by a joint discussion with the Manchester Section of the Oil and Colour Chemists' Association on the general rheological properties of suspensions.

Announcements

DR. H. R. HULME, sometime a chief assistant at the Royal Observatory and recently director of naval operational research at the Admiralty, has been appointed scientific adviser to the Air Ministry.

AT a meeting of the Council of the University of Sheffield held on December 14, the following appointments were announced: Mr. P. C. Sylvester-Bradley to be assistant lecturer in geology, and Dr. H. McIlwaine to be lecturer in biochemistry. Dr. A. Elliott, lecturer in physics, Dr. J. C. Speakman, lecturer in chemistry, and Mr. F. G. Hannell, lecturer in geography, have resigned.

THE All-Union Scientific Research Institute of Plant Industry of the U.S.S.R., made famous under the directorship of N. I. Vavilov, has returned to Leningrad from evacuation, and has begun to set its collections in order and to re-establish its exchanges of seeds and literature. None of the priceless collection of seeds has been lost. During the siege the Institute was guarded by five members of the staff who remained in Leningrad. This corrects the statement in the obituary article of Vavilov (*Nature*, **156**, 622; 1945) that "the residue of his collections was eaten by the famished people". Altogether about thirty members of the staff were killed or died of starvation during the siege. The director, Academician Eichwald, and the librarian, Mrs. Heintz, are anxious to resume exchanges. The address of the Institute is Ulitsa Gertsena 44, Leningrad.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.

Freedom for Scientific Research

In these days of 'planning' there seems a general desire by many, little qualified, to put science in its place.

The horrible threat that science was no longer to be international has been protested against, very rightly, by all that is best in the United States, Britain and elsewhere.

The idea that there should be two classes of men of science, one knowing government secrets and research work, and those outside the sacred fold, was, and is, a very shocking proposal. Now, I notice a school of thought that wants to plan fundamental research, forgetting that once you instruct anyone as to what they are to study, you are *ipso facto* imposing *ad hoc* research upon them.

I think it was the great J. J. Thomson who once said after the Boer War that if you had planned and organized science to explore the best way of finding bullets located in the human body, certainly probing might have become an art and the human body a pin-cushion, but not that way would there have been brought about X-rays. Mr. Herbert Morrison, I was delighted to see, speaking at the British Association, appreciated the point, and said you could not dragoon men of science relative to fundamental research. Well spoken.

Much remains to be done in planned *ad hoc* research by capable men to exploit (unpleasant word) for the good of all the discoveries of the laboratory. Here much can and should be done, for it is only by producing the most up-to-date and advanced design and technique that we can hope to export our goods in a world where every country is seeking to become industrialized.

We must appreciate that the pure scientist is a creative artist. No one must boss him. No one drive him. We are lucky in the production of these great men. Certainly arrange that their lives be free of monetary worries, but let us remember that their life interest and pleasure is research, and leave them to carry on undisturbed by the stormy blasts and distractions of a world licking its wounds and quarrelsome after a protracted fight. Do not of all things plan their lives. Some will produce future miracles no doubt, but most perhaps may not be so lucky. That should not worry us; our duty is to have given them the chance, and although many of their names may not be handed down to the future praised by all, yet they will have done good and noble work, for which we should all be no less grateful.

Brabazon of Tara.

Lognormal Distributions

In pointing the way towards easier manipulation of non-normal distributions, Prof. J. H. Gaddum's recent article[1] should act as a heartening stimulus to geologists. Sedimentary petrologists in particular will welcome it, for the efficacy of Prof. Gaddum's main theme is already established in certain
of their domain.

We are indebted chiefly to the American scl
Up to the present, most attention has been pai
the normalization of size distributions. The
and 'zeta' scales of Krumbein[2,3,4,5] are illustra
in this connexion, representing logarithmic tr
formations of the Wentworth and Atterberg
metric grade-scales. The transformations are car
out by substituting logarithms of the grade-s
limits for the appropriate diameter-values (ξ n
through

$$\varphi = -\log_2 \xi, \text{ and } \zeta = 0{\cdot}30\dot{1} - \log_{10} \xi.$$

They yield, of course, scales having arithmetic
tervals; hence the 'normal phi curve' (ref. 5, p. 2
and the direct application of conventional statis
to problems of sedimentary distribution. But
needs to recall that moment-analysis shows
sediments yield many local size-distributions w

Should such treatment prove vain, then reco
must be had to 'post-mortem' search (often
simpler of the two) succeeded by individual tr
formation of the variates. It must not be forgot
too, that the skewness and kurtosis of certain s
mentary variables (such as particle size measu
in terms of diameter) probably have consider
geological significance, and must not be lost
sight.

Distributions of sedimentary composition may
approached in the same way. Within geologic
'synchronous' horizons, the areal variation may
considerable (for example, up to 500 per cent
700 sq. miles in certain Lower Cretaceous rocks).
underlying variates (specific and varietal proportio
however, are seldom lognormal. A contributory ca
may be the complex relation that seems to e
between the compositional standard deviation
and the compositional mean (ρ_m). For actively s
ing, eroding or aggrading currents (providing
mean patchiness they impose is not widely differ
from ρ_m) this may be of the form

$$\sigma_h^2 = \rho_m^2 \left(J + \frac{1 - 2\rho_m}{L\rho_m^2} S\right) + \sigma_r^2,$$

where S is variable and related to the numbers
particles removed and added locally, σ_r is the rand
deviation and J and L are horizonal constants for
allogenic minerals[6]. If experiment should conf
this, then a general transformative panacea app
priate to each horizon may be proved to exist.
the other hand, a few mineral species and variet
do occasionally yield to transformations of the t
$X = \log(x_0 - x)$. (This is inevitably the prem
alternative to $X = \log x$ for those minerals wh
are liable to absent themselves locally.)

Neither can Prof. Gaddum's pertinent rema
concerning variance be overstressed to the geolog
No assumption of homogeneity of the variance wit
sedimentary universes should be lightly made,
be based where possible on rigorous test[7,8]. This
particularly urgent during detailed studies of 'patc
ness' by the analysis of variance when differences
locality are used as differences of 'treatment'. T

mentary petrologist, confronted in his quarry the solitary pebble embedded in fine silt, or rare particle locally so abundant, will most tily concur in Prof. Gaddum's advocacy of the its of the geometric mean.

PERCIVAL ALLEN.

ROF. J. H. GADDUM has dealt[1] comprehensively ı the subject of logarithmic transformations, uding $X = \log (x + 1)$. The use of this trans- nation was first advocated by Williams[2] on the ınds that it approximated to the logarithmic ısformation for large values of x, and avoided the iculty of a non-finite value of X when x was zero ; this argument is rather arbitrary, since the same ght be said of any function of the form, $\log (kx+1)$. o, the existence of zeros implies usually that many the values of x will be small and lie in the range ere $\log (x + 1)$ behaves like a square-root trans- mation. Consequently, some further investigation the properties of this function seems to be called

Since there are several instances[3,4] where a good rection for discontinuity has been found by add- $\frac{1}{2}$ to the variate, it appears possible that the nsformation, $X = \log (2x + 1)$, would have the vantages of $X = \log (x + 1)$ and would also cor- t the ordinary logarithmic transformation for dis- ıtinuity.

Two trials have recently been carried out to in- stigate empirically the properties of these two nsformations. Each was concerned with the mbers of fruits on apple trees. In the first there re four randomized blocks of seven treatments with en trees to a plot. It was thus possible to compute variance within plots with 24 degrees of freedom each treatment, and to compare the seven vari- ces thus obtained by evaluating the ratio of their ometric and arithmetic means. This quantity, own as L_1, has been tabulated by Nayer[5]. Using $\sqrt{x + \frac{1}{2}}$ transformation, L_1 was 0·863 ; for $(x + 1)$ it was 0·980 ; and for $\log (2x + 1)$ it s 0·982. The first of these values indicates a nificant departure ($P < 0{\cdot}01$) from uniformity in variances; but it will be seen that both the arithmic transformations were successful in equal- ng them. The mean numbers of fruits per tree the different treatments varied from 1·3 to 10·0, the values of the variate largely lay in the range ere discontinuity is serious and where $\log (x + 1)$ ost closely approximates to $\frac{1}{3}\sqrt{x}$. In the second al there were 64 pairs of trees of which 32 had en starved of potash while the rest had received equate fertilizer, the treatment means being re- ectively 8·3 and 12·5 fruits per tree and the ranges thin which the data lay being respectively 0–35 d 0–67 fruits. Variances with 32 degrees of freedom re worked out between trees within pairs within treatments. Using the transformations $\sqrt{x}$, $\sqrt{x + \frac{1}{2}}$, $\log (x + 1)$ and $\log (2x + 1)$, the values of L_1 were 0·968, 0·952, 0·9987 and 0·9998 respectively. Of these the second approaches the 5 per cent significance point, while the last two represent unusually good agreement between the variances. Indeed, such good agreement must be considered as partly fortuitous.

It would be rash to base much on the results of two small trials. However, there is reason to think that the transformation, $X = \log (x + 1)$, may be useful in dealing with small integral values despite the arbitrary element in its original selection, and despite its approximating sometimes to a square root and sometimes to a logarithmic transformation. It seems, also, that $X = \log (2x + 1)$ has at least an equal claim to be considered when such data are dealt with. It is to be hoped that this matter will engage the attention of some mathematical statistician, for it has obvious importance in the interpretation of a large class of data.

DR. ALLEN'S letter is welcome because it emphasizes the fact that no simple transformation can act as a panacea. The choice of the appropriate technique for any given problem must always be based, if possible, on direct evidence of its suitability. Another type of distribution has been discovered by Bagnold[1], who studied the distributions of the sizes of particles of sand deposited by wind. They were not lognormal, but when the logarithm of the diameter was plotted against the logarithm of the frequency, the observations were closely fitted by two straight lines. This fact presumably depends on the physical factors governing the deposition of particles from moving air, and may have many applications in geology. Such distributions can be normalized, but no simple general formula can be given since the slopes of the two lines may vary independently, and it is doubtful whether normalization would serve any good purpose. The logarithmic transformation is a useful tool; but, as Dr. Allen has emphasized, it must be used with care.

I should be glad to hear of more examples of lognormal distributions.

Kinematical Relativity

MY attention has been directed to Prof. H. Dingle's recent letter in *Nature*[1]. His supposed refutation of kinematical relativity is on a par with Dr. Samuel Johnson's refutation of metaphysics ; my failure to reply to him directly is due to my reluctance to engage in such trivialities. I have already given him all the answer he needs by referring him to my mathematical papers, where the case of the collision of equivalent particle-observers is fully dealt with. You cannot wantonly re-graduate any casual clock and expect to secure a consistent physics. Kinematical relativity does not do so. In kinematical relativity it is shown that for consistent time-keeping to be possible, the various particle-observers whose temporal experiences constitute clocks must be members of *equivalences*. Regraduation is applied only to such equivalences; and it was shown by Whitrow and myself[2] that if two members of an equivalence ever coincide, then *all members coincide at the same event*. This technical point is well known to all who have studied time-keeping in relation to equivalences; it is fundamental, for example, in some recent unpublished work by A. G. Walker. In its application, it means that in a contracting universe of time-keepers, there would be a singularity which would be the counterpart of 'creation' in an expanding universe. Prof. Dingle is concerned with the timing of 'subsequent events'; there would be no subsequent events—Prof. Dingle would not survive the catastrophe—just as in an expanding universe there are no events anterior to 'creation'. There are other objections to a contracting universe, but the 'absurdity' which preoccupies Prof. Dingle is a monster of his own construction which simply adds point to the absurdity of a contracting universe. As the universe is observed to be expanding, Prof. Dingle's difficulties never arise.

Prof. Dingle appears to resent my referring him to my published papers. I did so because I resent being continually required to re-traverse in the looseness of verbal statement ground carefully covered, with all due reservations, in the technical papers. Prof. Dingle has recently suggested that kinematic relativity cannot account for the red-shift in the spectra of the galaxies, whereas kinematical relativity is essentially the exploration of the properties of a cloud of mutually receding particles. If Prof. Dingle does not like clock-regraduation, let him content himself with the t-scale, which describes a consistent physics as it stands; only, he will have difficulty with reconciling its results with Newtonian mechanics unless he faces the fact that Newtonian mechanics employs the τ-scale, not the t-scale.

E. A. MILNE.

Wadham College,
Oxford. Oct. 15.

---

[1] *Nature*, **156**, 389 (1945).
[2] *Z. Astrophys.*, **15**, 277 (1938).

PROF. MILNE states that I have misapplied his principle of clock-regraduation. If so, Prof. Haldane has made the same mistake. The lamp-post example was his, and his letter[1] expressed his belief that Milne's transformation was applicable to it. The only difference between us was that he trusted that Milne could make his transformation "lead to the same predictions of observable events"—he stated that this could be done—and I did not. Now Prof. Milne fails him by denying the obligation.

Nevertheless, Haldane and I are right. In Milne's accounts of his theory (in "Relativity, Gravitation and World-Structure", for example), the right to regraduate clocks is first claimed on *a priori* grounds independent of applications. Only afterwards are equivalences defined as consisting of observers who impose a particular voluntary restriction on this general right. Now Prof. Milne wants to deny the right to all but these observers. On what grou Indeed, for that matter, are not the nose and la post members of an equivalence? They can fulfi conditions, and no minimum number of *a* observers is prescribed. Prof. Milne can, of co claim that he can make what arbitrary distinct he likes in an ideal hypothesis: in that ca challenge his right to call a romance a scier theory. If, on the other hand, he says that system of nebulæ provides an application for theory, then I ask why the student of nebulæ regraduate his clock, but not the student of la posts or meteorites.

Clock-Regraduations and Relativistic Cosmology

PROF. E. A. MILNE has severely criticized rela istic cosmology for several reasons, one being t this theory is restricted to a definite time-sc whereas his own theory admits of an infinite num of time-scales. Milne's construction of an 'equivale is invariant over a clock-regraduation, that is change from one time-scale to another.

In 1943[1], I suggested that the true analogue clock-regraduations in relativity theory was to found in Weyl's transformation of gauge. For metrics of relativistic cosmology, this reduces t change of the function γ in the line-element,

$$ds^2 = \gamma(r,t) \,.\, (dt^2 - dx^2 - dy^2 - dz^2).$$

It follows as a corollary to Infeld's[2] remarks th with this interpretation, Maxwell's equations a Dirac's equations are invariant over clock-regrad tions, while the relations of spherical symmetry a homogeneity are also preserved.

These remarks seem to dispose of one, at least, Milne's main criticisms of relativistic cosmology.

Adsorption Isotherms from Chromatographic Measurements

DE VAULT[1] has directed attention to the possibil of obtaining the adsorption isotherm of single solu from chromatographic results of the 'diffuse' boun ary, suggesting a differential equation for evaluati the measurements. A more useful equation can obtained by integration of the equation

$$v/x - \alpha = dq/dc,$$

where α and q are the pore space and the amou adsorbed per gram of adsorbent. After developi with a given amount of pure solvent v, the amou of solute μ remaining in the column between t tail end of the chromatogram and the point $\bar{x}$ wh the concentration $\bar{c}$ exists is

$$[\mu]_{\bar{c}} = \int_{c=0}^{c=\bar{c}} (q + \alpha c)dx$$

$$= \Big[(q + \alpha c)x\Big]_{c=0}^{c=\bar{c}} - \int_0^{\bar{c}} \left(\frac{dq}{dc} + \alpha\right) x dc \quad . \quad (2b)$$

$$= \overline{qx} + \alpha\overline{cx} - v\bar{c} \quad . \quad . \quad . \quad . \quad . \quad (2c)$$

Thus we obtain for the amount adsorbed

$$\bar{q} = f_{(\bar{c})} = ([\mu]_{\bar{c}} + v\bar{c})/\bar{x} - \alpha\bar{c} \quad . \quad . \quad . \quad (3)$$

Since μ is obtained experimentally as the total subsequent eluate in grams when $\bar{x}$ represents the length of the column, the complete adsorption isotherm can be obtained from a single chromatographic experiment simply by measuring the concentrations of successive eluted fractions.

The same integration can be carried out for two (and more) solutes. The fundamental equations for the mixed band of varying concentration

$$v/x - \alpha = dq_1/dc_1 = dq_2/dc_2 \quad . \quad . \quad . \quad (4)$$

require that co-existing values of c_1 and c_2 are functions of each other only; so that

$$q_1 = f_{(c_1 c_2)} = \Phi_{1(c_1)} \quad . \quad . \quad . \quad . \quad (5a)$$

$$q_2 = g_{(\bar{c}_1 c_2)} = \Phi_{2(c_2)} \quad . \quad . \quad . \quad . \quad (5b)$$

This means that within the diffuse mixed band the two solutes behave individually like single solutes, having an adsorption isotherm which is modified by the presence of the other solute. They follow the equations:

$$v/x - \alpha = d\Phi_{1(c_1)}/dc_1 = d\Phi_{2(c_2)}/dc_2, \quad . \quad . \quad (6)$$

where the functions Φ_1 and Φ_2 depend on f and g, and also on the initial concentrations c_1^0 and c_2^0. This makes it possible to integrate equation 6 in the same way as equation 1, resulting in:

$$\bar{q}_1 = f_{(\bar{c}_1\bar{c}_2)} = ([\mu_1]_{\bar{c}_1\bar{c}_2} + v\,.\,\bar{c}_1)/\bar{x} - \alpha\bar{c}_1 \quad . \quad (7a)$$

$$\bar{q}_2 = g_{(\bar{c}_1\bar{c}_2)} = ([\mu_2]_{\bar{c}_1\bar{c}_2} + v\,.\,\bar{c}_2)/\bar{x} - \alpha\bar{c}_2 \quad . \quad (7b)$$

The presence of the tail band of pure component I seems to complicate the procedure, but this is actually not so; it can be shown that the total amount contained in the pure tail band is identical with what it would contain if equation 6 were continued beyond the point x_0, where solute II becomes zero. Thus μ_1 actually represents the total amount of solute I—both pure and mixed—which remains in the column when the eluate reaches the concentration $\bar{c}_1$.

This method of determining the adsorption isotherms of binary mixtures was found to give accurate and reproducible results, provided that the chromatographic separation was carried out with negligible 'channelling' and sufficiently slowly, so as to reach local equilibrium between solution and adsorbent everywhere. Several elution experiments using widely different ratios of c_1^0/c_2^0 are required to cover the whole range of a binary adsorption isotherm. Details and experiments will be published in due course.

Incidentally, if equation 7*a* is applied to the state of complete chromatographic separation of two solutes (by making $\mu_1 = m_1$, that is, the total solute I, $c_1 = c_1' = [c_1]_{c_2=0}$ and $x = x_0 = v\,.\,[\alpha + dg_{(c_1 0)}/dc_2]^{-1}$), this leads to the volume of pure solvent V required for complete separation:

$$V = m_1 \,.\, \frac{\alpha + g'_{(c_1'0)}}{f_{(c_1'0)} - c_1' \,.\, g'_{(c_1'0)}}, \quad . \quad . \quad (8)$$

which is in agreement with equation 6 of an earlier communication[2] where α had been neglected.

Efficacy of D.D.T. in Soap

ONE of the remarkable features of the successful use of D.D.T.-impregnated clothing against the louse is the prolonged insecticidal effect of the clothing after several launderings, which would appear to indicate a strong absorption of the compound on the textile fibres. It occurred to us that animal hair might behave in the same way, and that useful results might be obtained in veterinary practice by the simple expedient of incorporating D.D.T. in soap[1].

Rather more than a year ago, we began experiments using varying proportions of the insecticide milled with household soap, and through the kindness of several dog owners and veterinary surgeons we were enabled to arrange practical trials. Twelve dogs were treated, including spaniels, sheepdogs and other long-haired breeds, having infestations either of the dog flea, *Ctenocephalus canis*, or the dog louse, *Trichodectes canis*, varying from slight to heavy. The animals were washed with the soap and warm water for 10–15 minutes, then rinsed down and rubbed dry in the usual manner. All fully grown parasites on the dogs were seen to be killed by this treatment. Seven of the dogs were kept under observation for a further three months, during which period they were freely exposed to re-infestation. The first sign of this appeared nine weeks later, and was limited to one animal, the others remaining free from re-infestation for the duration of the trials. In two instances eggs of the insects were known to be present, but these failed to hatch during the normal period. It therefore seems that a considerable degree of immunity from such parasites can be conferred upon animals by washing with D.D.T. soap, and this should be of importance not only to dog owners, but also to farmers and animal breeders in general.

With the view of estimating the amount of insecticide left on the hair, we analysed samples from treated and untreated animals by solvent extraction, and found that the percentage of hydrolysable chlorine in untreated hair was 0·002 per cent, whereas treated samples ranged from 0·005 to 0·007 per cent, equivalent to 0·05–0·07 per cent of D.D.T. It is surprising that these minute amounts of D.D.T. should give such a lasting effect. In the case of clothing impregnated with D.D.T., a concentration of only 0·01 per cent of the compound in the impregnation solution gave surfaces displaying noticeable insecticidal properties against the louse[2]. It would appear, therefore, that there is a similar absorption on the surface of the hair which prevents the D.D.T. from being washed off with the soap medium. Experiments to examine the mechanism further are in hand.

Differentiation of Nuclear Substances

One of the most used reactions of the clinical-chemical laboratory is the sedimentation reaction of the erythrocytes. It has been shown that sedimentation is hastened if, in consequence of physiopathological occurrences in the organism, the protein fractions of high molecular weight (fibrinogen, globulins) have increased[1].

We were able to demonstrate by means of some typical reactions[2] that the sedimentation reaction is chiefly of an unspecific nature and occurs with polysaccharides as well as with plasma proteins. We have succeeded, by fractional precipitation of the spherical colloid glycogen with methanol, in separating polymers of high molecular weight with diameters of approximately 100 glucose molecules from polymers with diameters in cross-section about ten times smaller. These different fractions of polymers produce accelerations of sedimentation which vary in accordance with their average particle size. This interdependence was shown with still greater accuracy with the rod-shaped molecules of apple pectin[3]. These long, partly methylated chain molecules of galacturonic acid are easily disaggregated by neutral hydrolysis. In proportion to this hydrolysis it is possible to measure the diminution of viscosity, the scattered light (Rayleigh), as well as the effect on acceleration of sedimentation.

After these preliminary experiments the following tests were made and compared: adenylic acid from yeast (mononucleotid, mol. weight 347), yeast nucleic acid (tetranucleotid, $C_{38}H_{49}O_{29}N_{15}P_4$, mol. weight 1303) and thymonucleic acid kindly provided by Prof. Rud. Signer (mol. weight 600,000–1,000,000)[4]. The last-named substance accelerated the sedimentation of erythrocytes even in a concentration of 6 mgm. per cent in measurable extent. On the other hand, the yeast nucleic acids produced no effect even in a concentration of 400 mgm. per cent. A provisional review of these effects follows.

From fresh human blood the erythrocytes are washed three times with saline on the centrifuge, in order to attain a suspension of 100 per cent in the end. 5 mgm. of the nucleic acids are first dissolved in 0·5 c.c. of homologous serum and then diluted with 0·5 c.c. saline. Then 5 mgm. of glycogen, gelatine and pectin are first dissolved in 0·5 c.c. saline and then diluted with 0·5 c.c. serum. Now we mix carefully 0·3 c.c. of these solutions with 1·2 c.c. of the 100 per cent erythrocyte suspension. With this the concentration of the nucleic acids and the polysaccharides is brought to 100 mgm. per cent. Five minutes later the suspensions are drawn up in original Westergren pipettes, and the sedimentation read off in mm. in corresponding periods:

Additions to erythrocytes	Sedimentation (min.)						20 hours
	10	20	40	60	90	120	
Serum and saline only	—	—	—	0·5	1	1·5	16
Adenylic acid from yeast	—	—	—	0·5	1	1·5	16
Nucleic acid from yeast	—	—	—	0·5	1	1·5	18
Thymonucleic acid	1·5	9	23	61	83	96	115
Glycogen	—	—	—	0·5	1	1·5	18
Gelatine	—	—	1	2	4	6	35
Pectin	2	26	89	116	119	120	123

The superior effect of the high molecular thread-like molecules of the sodium salt of thymonucleic acid (desoxyribonucleic) compared with the yeast nucleic acids (ribonucleic) is evident. Since both types of nucleic acids are polymers of mononucleotides it follows that the new way of differentiating between them depends on their particle-size rather than on the different constitution of their ribose component. The exact interdependence of the molecular weight and the acceleration of the sedimentation of the erythrocytes could be proved with a sequence of homologous polymers like polystyrol for example. If such synthetic polymers were to be tried, one would have to ascertain that they do not possess hæmolytic properties. The substances mentioned above have none, and moreover the serum makes an excellent buffer.

Influence of Blood Pressure and Blood Flow on the Activity of the Respiratory, Vasomotor and Cardio-Regulatory Centres

The classical opinion is that changes in the central blood flow and blood pressure affect and regulate in a direct central manner the activities of the respiratory and cardio-vascular centres: decrease of central blood pressure or blood flow was considered to stimulate directly the respiratory and vasomotor centres and to inhibit directly the tone of the vagal cardio-inhibitory centre; increase of central pressure or flow was considered to induce directly the opposite central reactions. Although numerous experiments performed by several different methods had shown[1] that blood pressure and blood flow changes occurring in physiological and physio-pathological conditions affect the activities of the respiratory and cardio-vascular centres not through a *direct* central action but only *reflexly* by way of the presso-receptor nerves of the aortic and carotid sinus areas, the classical theory of direct central regulation is still supported, particularly as regards the physiological control of the respiratory centre[2]. As this point is of fundamental theoretical importance, I have investigated the problem.

Experiments were performed on dogs anæsthetized with chloralosane; systemic arterial blood pressure, heart frequency and respiratory rate, amplitude and volume were registered. The experimental results may be summarized as follows.

(*a*) Occlusion or desocclusion of the efferent arteries (internal and external carotid and occipital arteries) of the common carotid arteries do not affect the activity of the respiratory and cardio-vascular centres.

(*b*) Occlusion or desocclusion of both vertebral arteries, alone or simultaneously with the efferent arteries of the common carotid arteries, also do not affect the activity of the respiratory and cardio-vascular centres, although the occlusion and release of these very important and main cerebral arteries induce very marked changes in the central blood pressure and blood supply.

(*c*) Decrease up to about 75 per cent of the normal blood supply or blood pressure to the isolated and perfused cerebral circulation does not stimulate directly the respiratory, vasomotor and cardio-regulatory centres.

(*d*) The isolated cephalic circulation being perfused means of the two common carotid arteries only, clusion of the common carotid with normal in- rvated carotid sinus induces a stimulation of the spiratory centre, while the occlusion of the common rotid with denervated carotid sinus does not stimu- te the respiratory centre.

(*e*) Decrease of blood pressure in the circulatory olated but normally innervated aortic or carotid nus presso-sensitive areas induces, as shown reviously[1], a reflex stimulation of the activity of the spiratory and vasomotor centres and a reflex in- bition of the vagal cardio-inhibitory centre; in- ease of blood pressure in the same presso-sensitive terial areas induces reflexly a respiratory inhibition, ecrease of general blood pressure and slowing of the eart.

These experimental results thus show conclusively at: (1) Changes of the central blood supply or blood ressure within physiological, but not to extreme hysio-pathological, limits do not affect directly but flexly the activity of the respiratory and cardio- ascular centres; (2) physiological or physio- athological variations of the arterial blood pressure ct reflexly, by means of the aortic and carotid sinus resso-receptors, on the activity of the respiratory nd cardio-vascular centres.

These experimental facts thus do not support the neory of the physiological regulation of the activity f the respiratory and cardio-vascular centres by neans of their own internal metabolic rate. Never- heless, as shown by previous experiments of our boratory[1-3], extreme pathological modifications of ne central blood supply may affect directly the espiratory and cardio-vascular centres; but these fluences have no practical importance for the *hysiological* control of respiration and the circulation. hese experimental facts also show once more that ypoxæmia does not stimulate the respiratory centre irectly, but reflexly by means of the chemoreceptors, nd are in favour of the probability of a specific unction of the carbon dioxide in respiratory control.

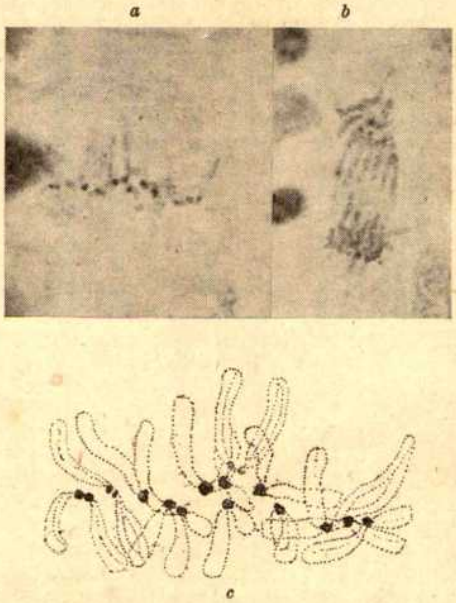
Cytological Reactions Induced by Inorganic Salt Solutions

AN investigation has been carried on for some time a this Laboratory into the immediate cytological ffect of salt solutions on root meristems of *Allium 'epa*. Salts, mostly nitrates, of some forty metals rere tested. A dilution series of 10–16 concentrations rere studied for each substance, covering the whole ange from total lethality down to such weak concentrations that no cytological effect could be detected. Fixations of root tips were made after 4 and 24 hours respectively. All slides were stained with crystal-violet.

A rather surprising result of these treatments was the very common occurrence of colchicine mitosis. Full and typical colchicine mitosis was met with in different concentrations of salt solutions of the following metals: lithium, beryllium, sodium, potassium, chromium, iron, cobalt, nickel, copper, arsenic, rubidium, yttrium, palladium, cadmium, barium, lanthanum, cerium, neodymium, erbium, gold, mercury, thallium, lead, bismuth and thorium. Almost all the substances tested showed at least some tendency to spindle disturbances such as are typical of incipient colchicine mitosis.

In many cases the activity threshold of colchicine mitosis was considerably lower than it is in colchicine, for example, in cupric nitrate, yttrium sulphate, lanthanum nitrate, auric chloride and lead nitrate, where it was situated at 0·000005–0·00005 mol., that is, at the degree of activity of acenaphthene. On surveying the whole material, a tendency of the threshold values to fall with increasing molecular weight was observed. In the fifth, sixth and seventh periods of the periodic system, all threshold values lie below 0·0005 mol., while in the second and third periods several thresholds lie as high as 0·05–0·2 mol. Especially such salts as are among the nutrients of plants have high threshold values (that is, low colchicine mitotic activity).

Several of the tested substances induced colchicine mitosis which in morphological details as well as in completeness was indistinguishable from the typical cochicine-induced mitosis. Such was the case, for example, with lead nitrate and potassium cyanide. Otherwise, the colchicine mitosis induced by salt solutions was found to show a greater variation in type than is found after treatment with organic substances. Thus, it was often incomplete: at several steps of the dilution scale it might occur intermingled



Allium Cepa, MITOSES OF THE ROOT MERISTEM, ROOTS TREATED FOR FOUR HOURS WITH 0·005 MOL. MERCURIC NITRATE; *a*, METAPHASE, × 1050; *b*, ANAPHASE, × 1050; *c*, CONTOUR DRAWING OF *a*, × 2100.

with normal mitoses. Other deviations from the normal course of colchicine mitosis, some of which have been described earlier from material treated with colchicine (Barber and Callan[1]), were: 'star-metaphase' (induced by, among other substances, lithium nitrate), 'ball-metaphase' (arsenious oxide), and 'bow-metaphase' with long arched chromosomes scattered over the cell (lanthanum and cerium nitrates). A peculiar type of mitosis, the mechanism of which may be quite unrelated to colchicine mitosis, was induced by nickel nitrate: the chromosomes behave as in colchicine mitosis, although a clearly visible spindle is present.

The colchicine-tumour reaction, which on treatment with organic substances usually accompanies the colchicine mitosis, is rarely present when inorganic salts are used for the induction of this form of mitosis. Nevertheless, there often occur characteristic growth disturbances: the roots become bent into hooks or even wound into spirals. This reaction may represent incomplete colchicine-tumour growth.

A reaction which is found only in exceptional cases after treatment with organic substances, but which was of rather general occurrence in the present experiments, is the induction of sticky chromosomes, manifested mainly by the formation of anaphase bridges. Pronounced stickiness was observed in the following treatments: lithium, beryllium, aluminium, titanium, chromium, iron, cobalt, nickel, copper, arsenic, yttrium, zirconium, molybdenum, palladium, cæsium, lanthanum, cerium, neodymium, erbium, tungsten, gold, mercury, thallium, bismuth, thorium and uranium.

Many of the salts tested caused deviations in the staining qualities of the chromosomes. Thus, during the contraction stages, the ability to take the stain was often decreased. At the same time the internal structure of the chromosomes was revealed more clearly than normally. At metaphase the chromatids were widely apart, although coiled around each other. Each chromatid was clearly divided, and the space between the two half-chromatids was sometimes so considerable that the phenomenon cannot be due to an optical error. The half-chromatids often formed a relational spiral of great clearness. After these observations, I am convinced that the metaphase and anaphase chromatids of *Allium* are really divided. Especially illuminative in this respect was treatment with sodium fluoride, sodium molybdate, sodium tungstate, auric chloride, mercuric chloride, and phosphate – sodium hydroxide buffers. Although this reaction is subvital or lethal, its significance for the interpretation of vital structures is indisputable.

In several of those treatments which brought about a tendency of the chromosomes to stain very faintly, it was observed that the heterochromatic regions still stood out deeply stained when all colour had left the rest of the chromosomes. In fact, some of the treatments allowed a differential staining of the heterochromatin at metaphase-anaphase. This condition was found after treatment with beryllium, sodium, titanium, cobalt, yttrium, antimony, cerium, gold, mercury and others. The most delicate differentiation between euchromatin and heterochromatin has so far been found after treatment with mercuric nitrate in concentrations just above the fixing threshold. It can be seen from the accompanying illustration that the 'body' of the chromosomes is very weakly stained, while small darkly stained portions are present, one on each side of the centromere of each chromosome. The greater part of the hete chromatin of this variety of *Allium Cepa* is localiz to the vicinity of the centromeres.

Carboxylase and Carbonic Acid

It is generally understood that, in the action carboxylase on pyruvic acid or other allied keto aci carbon dioxide is directly split off. The followi experiments show that this is not so, but that ca bonic acid is first formed, the process contrasti with urease action in which carbon dioxide is direct produced in the splitting of urea. (This latter h been investigated by Roughton and Krebs[1] wi respect to the action of carbonic anhydrase, and t present study of carboxylase is suggested by the procedure.)

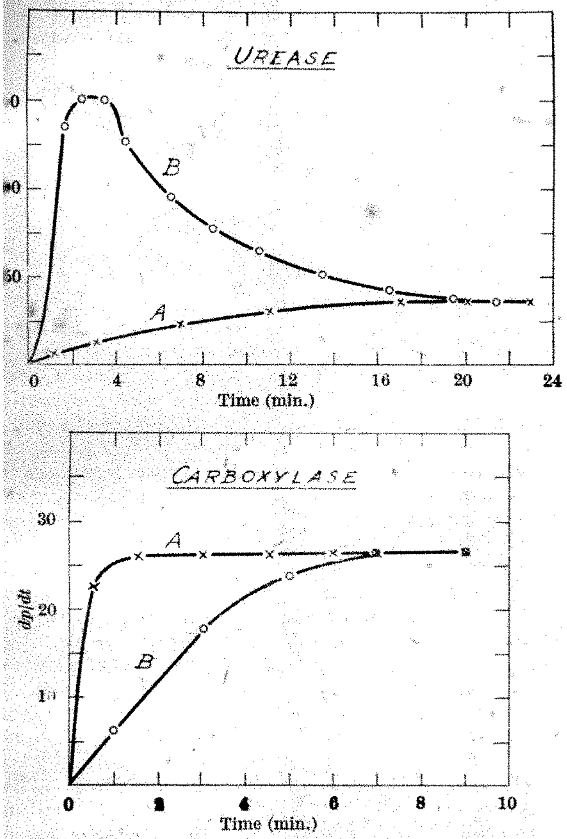
Sodium pyruvate was acted upon by a carboxyla solution in the presence of carbonic anhydrase pr vided by some laked rabbit blood, the whole at *p*H of 5·5. The course of the carbon dioxide evolutio was followed manometrically at 37° C. The exper ment was repeated with cyanide-treated blood (t inhibit the carbonic anhydrase), the *p*H of the mixtu being also 5·5. The conditions were as follows 1 c.c. of a yeast carboxylase preparation; 0·2 c. laked rabbit blood (1 in 12·5, with total carbo dioxide removed); 0·5 c.c. 20 per cent sodiu pyruvate, *p*H 5·5, added from side tube after equil bration. Similar experiments were carried out i which a urease preparation (buffered with phosphate was substituted for carboxylase and 5 per cent ure for sodium pyruvate, the *p*H of the whole being 6·8

In following the course of the evolution of carbo dioxide in the Warburg manometer, when the heigh of the fluid in the free limb of the manometer (th other being adjusted to the usual 150 mm. mark reached 300 mm., the vessel was immediately con nected momentarily with the atmosphere, and th levels rapidly adjusted to 150 mm., the experimen being then continued as before, and the pressur developed (in mm.) added to the previous sum. Thi procedure no doubt introduces some error, but of kind that has no significance for the question exam ined. From the data obtained the derivative dp/d was plotted against the time, with the results show in the accompanying graphs.

The urease curves show the same features as give by Roughton[1], namely, an initial rapid developmen of pressure contrasted with a smooth movemen towards a steady state in the presence of active car bonic anhydrase. The picture with carboxylase show essentially the opposite features, a rapid pressure development with active carbonic anhydrase, and comparatively slow rise of the curve in its absence

Theoretically, the picture with carboxylase (pro ducing carbonic acid) should not be the exact opposite of that with urease (producing carbon dioxide). With the former an over-fling of the upper curve would not be anticipated, and does not in fact occur.

The results show that carboxylase forms carbonic acid directly, and not free carbon dioxide. This con clusion is supported by the fact that the total carbon dioxide in the suspending fluid of a fermenting yeast mixture (with high proportion of yeast) is far highe



4, WITH *active* CARBONIC ANHYDRASE ; *B*, WITH *inactive* CARBONIC ANHYDRASE.

ian could be accounted for by free carbon dioxide r bicarbonate ions.

With the formation of carbonic acid by yeast arboxylase acting on pyruvic acid, it is very probable that it is also formed by similar ferments acting i animal tissues. This would affect rather much he detailed picture of carbon dioxide passage from issues to blood as hitherto given.

Packing of Regular (Spherical) and Irregular Particles

MESSRS. BROWN AND HAWKSLEY have stated[1] that ie figures given by Mr. Ackermann[2] are apparently icorrect. As these figures were obtained by Mr. ckermann and myself working in conjunction, I iould like to state their exact meaning.

It is stated by Messrs. Brown and Hawksley that ie voidage is independent of the size of the container, rovided its shape and size are such that it will ontain an integral number of unit cells of the articular ordered arrangement. The figures given y Mr. Ackermann deal precisely with cases where ie container does *not* contain an integral number of units, but nevertheless the spheres are packed in an ordered fashion, and this is rhombohedral (each touching twelve), but not necessarily entirely so. He deals with cases where the diameter of the sphere is an aliquot part of the side of the cube, say $1/n$th. The spheres are then packed in alternate layers of n^2 and $(n-1)^2$ spheres, which in the case of a cube will normally leave a space at the top which cannot be utilized. In some cases, however, the space left is sufficient to convert an $(n-1)^2$ layer into an n^2 layer, and in this case the rhombohedral packing is not adhered to for this layer. The question that we were dealing with was the maximum number of spheres (the diameter being an aliquot part of the side) which could be packed into a cubical box by an ordered arrangement. I append a more detailed list of the figures obtained by Mr. Ackermann and myself.

Max. number of spheres in a row = n	Total number of spheres in box	Voidage
5	132	0·448
6	244	0·411
7	402	0·386
8	580	0·407
9	870	0·378
10	1,205	0·369
20	10,332	0·321
30	36,561	0·292
40	87,388	0·285
50	171,535	0·282
100	1,396,070	0·269

In the case where $n = 5, 7, 8, 10, 20$, it is found possible to change an $(n-1)^2$ layer into an n^2 layer.

The limiting voidage when the particles become infinitely small is $1 - \frac{\pi\sqrt{2}}{6} = 0{\cdot}2595$.

Since Messrs. Brown and Hawksley state that spheres when poured into a box take up a disordered arrangement with a voidage between 0·45 and 0·37, it will be seen from the above table that there is considerable advantage in the packing suggested. I do not think that any other ordered arrangement will give a greater number of spheres in a cubical box than is shown by the above figures.

Mode of Entry of Contact Insecticides

Potts and Vanderplank[1] deduce a relation between the size of the pulvilli and the speed of action of contact insecticides. This would follow, as, to kill an insect, a lethal dose of the insecticide is required to be transferred to it. The larger the pulvilli, the larger the dose of insecticide the insect will collect when it alights on a treated surface. The speed of action of various modern synthetic insecticides, however, shows wide variation.

In some experiments with various types of animal lice (*Hœmatopinus suis*, *Trichodectes latus*, etc.), insecticidal wax sticks were made up containing 10 per cent of insecticide in a mixture of beeswax, paraffin wax and soft white paraffin. By wiping pieces of khaki serge very lightly with the sticks, a thin film of the material was transferred to the fibres of the serge in the form of fine sheaths of the waxy compound around the individual fibres. The pieces of serge were then fastened over the top of glass jars and belled inwards. The insects were introduced and prevented from straying by pieces of transparent cellulose fastened over the mouth of the jar. Lice came into contact with the insecticidal wax through the tarsal claws hooking around the sheathed fibres. When *n*-carbitol thiocyanate was used, the lice were dead in six minutes, whereas with D.D.T. the lice were not dead until the lapse of 120 minutes.

In these experiments, contact between the insects and the insecticides was almost entirely through the medium of the tarsi; and as, in these insects, the pulvillus is but little developed, it is unlikely that the relative size of the pulvillus has any special significance except as mentioned above.

Ergot on *Pennisetum Hohenackeri* Hochst.

Pennisetum Hohenackeri Hochst. (*P. alopecuros* Nees) is a densely tufted perennial grass thriving in the clayey moist situations. The occurrence of sphacelial and sclerotial stages of a *Claviceps* on this host was first recorded by Ajrekar[1] in the course of his studies on the sugary disease of jowar in India caused by *Sphacelia Sorghi* McRae. In their studies on the ergot in South India, Thomas *et al.*[2] have given measurements of the spores of the *Sphacelia* and of the sclerotia. The honey dew forms a brownish viscid crust on the infected spikelets, embedding numerous spores. The spores are hyaline, thin-walled, 17–24 × 3–7 μ.

The ergot and sphacelial stages on *Pennisetum Hohenackeri* were collected round about Bangalore during the months of February and March. The collection of the sclerotial stages is rendered difficult at later periods on account of their dispersal by wind in the same manner as normal seeds. The persistent bristly glumes help in the process of dispersal. The identity of the *Claviceps* species has so far remained obscure on account of the lack of germination stages.

For germination, well-developed mature sclerotia were taken after dissecting out the enveloping glumes. These were wrapped up in a wire gauze and buried in dry soil placed in a pot in the greenhouse. Care was taken to prevent any extraneous moisture from soaking into the pot. The sclerotia were taken out after a month, treated with 0·5 per cent solution of potassium permanganate, washed in water and placed buried in sterilized moist sand in petri dishes. The germination of sclerotia was noticed after 20–30 days, the first indication being the rupture of the cortex of the sclerotium and the extrusion of a white globose head. This ascigerous sphæridium enlarges in diameter and is pushed upwards by the developing stipe or stem. In mature stages the ascigerous head portion is maroon red with a pinkish tinge, the stipe being pure white in colour. The surface of the sphæridium is papillate on account of the protrusion of the apices of the ostioles, and measures about 1–1·5 mm. in diameter. The stipe measures abo 20 mm. in length and shows a tendency to turn a twist as described by Whetzel and Reddick[3] a others.

The colour of the stroma, the size of the perithe and the ascospores indicate that the species com nearest to, or is identical with, *Claviceps microcephe* (Wallr.) Tul. Petch[4], who made a detailed study *C. purpurea* and *C. microcephala* on *Lolium perenn Glyceria fluitans*, *Festuca arundinacea* and others, co cluded that there were no morphological grounds f separating the two species, and reduced *C. mic cephala* as a synonym of *C. purpurea*. Both the species of *Claviceps* were founded by Tulasne, which *C. microcephala* is always distinguished by t smaller size of the sclerotia, which according Hartwich (Tubeuf and Smith[5]) contain three tim as much ergotin as those of *C. purpurea*. Wh further studies are yet needed to validate Petc conclusions, it seems reasonable to place the *Clavice* species on *Pennisetum Hohenackeri* under *C. mic cephala*.

Classification and Nomenclature of Animal Behaviour

IT was suggested in a recent communication[1] th kineses be designated as positive and negative, as done with taxes. The arguments advanced agains the use of 'high' and 'low' for kineses still stand, bu after discussions with other workers and some ex perience of applying positive and negative to specif cases of kineses, these terms do not appear sati factory. For the sake of clarity it seems desirable t apply to kineses terms different from those applie to taxes.

In what has been called a 'high' or 'positiv kinesis the situation is summed up by saying the is a direct relation between temperature and activity in a 'low' or 'negative' kinesis there is an invers relation between them. The straightforward cours is, therefore, to call the former a '*direct* kinesis', an the latter an '*inverse* kinesis'. Thus, when a hig stimulation intensity is associated with a high lev of activity, or low stimulation with low activity, w are dealing with a direct kinesis; when a high stimu lation intensity is associated with a low level activity, or low stimulation with high activity, w are dealing with an inverse kinesis. Dr. D. L. Gun who was among those not entirely satisfied with th proposal to apply positive and negative to kineses[2] informs me that he considers the above new suggestion do meet the case.

Duration of Life of Woodlice

Some little time ago I published a note on the uration of life of certain species of woodlice[1] which ad been studied by Major Stanley S. Flower and ne, and it was there recorded that Major Flower ad kept a specimen of *Oniscus asellus* Linn. (born n captivity) for approximately 4 years 8 months and 8 days or possibly 4 years 9 months 20 days. My wn record for this same species was 4 years 3 months days.

Major Flower has now very kindly sent me a emale specimen of this species, 18·5 mm. in length, vhich was born in captivity between June 13, 1940, nd August 31, 1940, and died on August 16, 1945. This specimen was thus certainly 4 years 11 months 6 days old and possibly 5 years 2 months 3 days. Apart from the record for *Platyarthrus hoffmanuseggi* Braudt[1] which I kept alive, in captivity, for 5 years months, these constitute the only records I know f where these isopods lived for more than five years.

A further interesting point in Major Flower's letter is the following. Speaking of the above-mentioned specimen he writes, "I have looked at it every day and on August 15, 1945, it appeared to be quite healthy . . . and it was very tame and appeared to enjoy my stroking it with a finger".

Steam Tables and Steam Power

In a recent review of "The 1939 Callendar Steam Tables"[1], Dr. H. Heywood concludes by saying that "these tables . . . should meet the requirements for many years of engineers concerned with the design and testing of steam power plant or of heating and ventilating systems". In the light of recent advances in technology and metallurgy this may be thought to be an optimistic forecast. Boiler plant design during fifty years has been consistently ahead of the accurate thermodynamic data upon which it should be based, and the 1939 steam tables can only be said to have caught up with modern practice, leaving little margin for further development in the direction of improved power-cycles.

In our view there are important theoretical considerations which point to an immediate need for extending the data into the unexplored area of the temperature-entropy plane bounded by the temperature range 600°–1,600° F. and the entropy range 1–1·5 B.Th.U. per lb. deg. Fahr. Thus, although a direct extrapolation of the enthalpy data gives no indication of any change in the trend of the pressure-enthalpy relation in this region, the corresponding data calculated from a reduced equation of state indicate the occurrence of a pronounced minimum. The van der Waals' equation, for example, leads to a minimum value of enthalpy when

$$\frac{8t_r}{(3v_r-1)^2} - \frac{6}{v_r^2} = 0;$$

which for steam gives the following values of volume and pressure at three selected temperatures :

Temperature (° F.)	Volume (cub. ft./lb.)	Pressure (lb./sq. in.)
980	0·029	14,000
1340	0·032	19,500
1700	0·035	29,500

The accuracy to be expected from any simple equation of the form $p_r = f(t_r, v_r)$ in the region delineated is, however, not great, and from the point of view of defining conditions for maximum theoretical efficiency direct observations are required.

There should be no insuperable experimental difficulties in exploring this region, since although high pressures are involved the corresponding specific volumes are small. Moreover, the advantages to be derived from the possibility of passing, without phase separation, from supercooled liquid to superheated vapour are considerable, particularly in respect of heat transfer.

A PHOTO-ELECTRIC FOURIER TRANSFORMER

By PROF. MAX BORN, F.R.S., DR. R. FÜRTH, and R. W. PRINGLE
Department of Mathematical Physics, University of Edinburgh

THE 'Fourier transform' $g(y)$ of a function $f(x)$, usually defined by the integral

$$g(y) = \frac{1}{\sqrt{2\pi}} \int_a^b f(x) e^{-iyx}\, dx, \quad . \quad . \quad . \quad (1)$$

plays an important part in many problems of pure and applied physics. It represents, for example, the connexion between the intensity distribution of a wave scattered by matter of a certain density distribution, which has to be calculated in a number of acoustical and optical problems and, above all, in X-ray crystal analysis work. It further allows the resolution of a complicated oscillation into a continuous frequency spectrum of harmonic oscillations, which is required in many problems of mechanical and electrical engineering. It therefore seems of some importance to have an instrument by which the Fourier transform of a given function can be automatically and quickly produced. We have now succeeded in building up an instrument which produces the graph of the function

$$g'(y) = \int_a^b f(x) \cos(yx + \delta) dx \quad . \quad . \quad . \quad (2)$$

on the screen of a cathode ray oscillograph, from a mask cut out of black paper in the shape of the graph of the function $f(x)$, or from a record of this function on a plate or film in density variation. Obviously two of the functions $g'(y)$ for two values of δ, say, $\delta = 0$ and $\delta = \pi/2$, are equivalent to the complex function $g(y)$ when $f(x) = 0$ for $x < a$, $x > b$.

The method is a photo-electric one, based on a similar principle to that used by Montgomery for discrete Fourier analysis, but extended for continuous Fourier analysis, that is, Fourier integration. A pattern of parallel fringes, with the light intensity varying according to a harmonic function in a direction normal to the fringes, is projected on the mask (or record) mentioned above representing the given function $f(x)$, and the transmitted light is concentrated on the cathode of an electron-multiplier vacuum photocell. The anode current through the cell will then obviously be proportional to the right-hand side of the expression (2) for a given spacing $2\pi/y$ and setting δ of the fringe system. y is now made to vary periodically in time, that is, the fringe system is made to extend and shrink periodically in the following way.

A glass disk, carrying a photographically produced fringe pattern in which the transparency varies sinoidally, is rotated about an axis perpendicular to its own plane. It can be set so as to let the axis intersect the pattern either at a point of minimum density ($\delta = 0$), or maximum density ($\delta = \pi$), or half-way between two such points ($\delta = \pi/2$), or for any other phase required. The disk is evenly illuminated with light from a projector lamp, and a real image of the fringes is produced on an opaque screen with a narrow adjustable slit in it, the axis of rotation of the image passing precisely through the centre of the slit. The light intensity along the slit will then be a sinoidal one with a spacing which shrink and extends periodically in time as the disk rotate Finally, by projecting an image of the slit on th plane of the mask (or record) by means of a cylindric lens, with its cylinder axis at right angles to the sli the optical arrangement is completed.

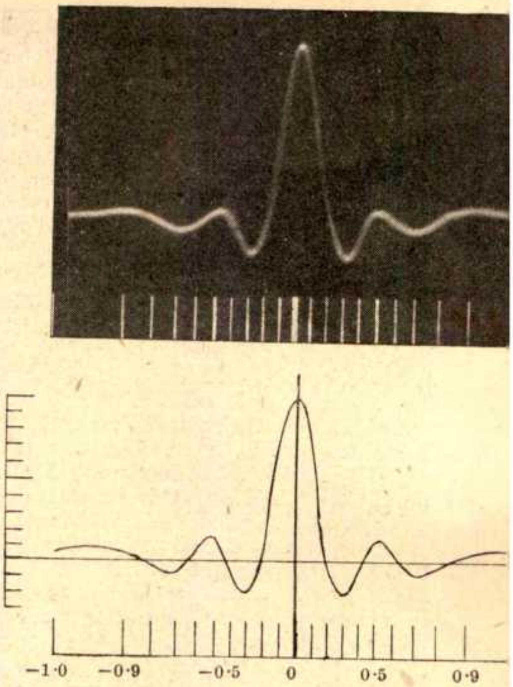

Fig. 1. Above : Record of the Fourier transform

$$g'(y) = \int_0^a C \cos yx dx \simeq \frac{\sin ay}{y}$$

Below : Calculated graph of the same function.

In order to produce the graph of the Fourie transform, the voltage across a resistance in the anod circuit of the photocell is transferred to a cathod ray oscillograph with which is incorporated a tw stage linear amplifier, and a harmonic time base i supplied, synchronized to the rotation of the dis As the replacement of one mask (or record) by an other one, the setting of the phase, and the photo graphing of the trace take only a couple of minutes the new method is apparently capable of producin the required Fourier transforms in a minimum o time.

Figs. 1 and 2 show some examples of the perform ance of the instrument. The records were produce by using the incorporated linear time base of th oscillograph, instead of a harmonic time base, whic has the effect of making the horizontal scale of th graphs non-linear. The correct scale has been inserted at the bottom of each graph. Fig. 1 shows (above) the actual record of the Fourier transfor

$$g'(y) = \int_0^a C \cos yx dx \simeq \frac{\sin ay}{y}$$

and (below) the calculated graph of this function, and gives an idea o the accuracy of the instrument. Fig. 2 shows the records of four other Fourier transforms. We have satisfied ourselves also that in these and many other cases the curves obtained coincide with the calculated ones within the limits of accuracy of the present instrument.

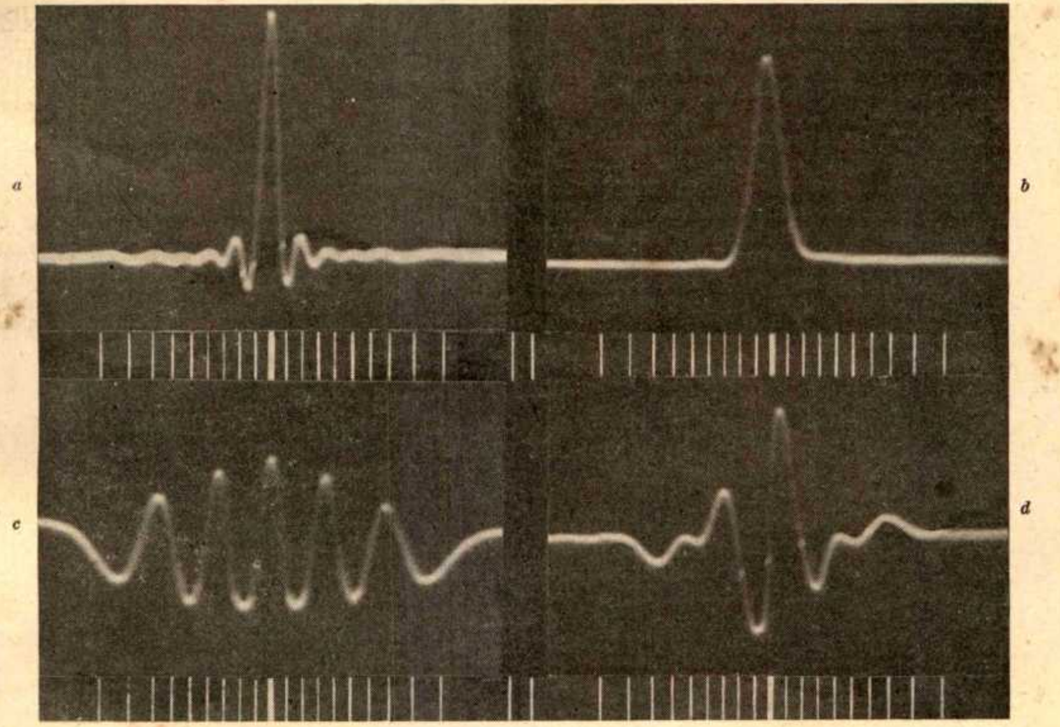

Fig. 2. Records of the Fourier transforms:

(a) $g'(y) = \int_{-A}^{+A} C \cos yx dx \simeq \frac{\sin Ay}{y}$; $(A = 2{\cdot}3a)$;

(b) $g'(y) = \int_{-A}^{+A} e^{-bx^2/2} \cos yx dx \sim e^{-y^2/2b}$;

(c) $g'(y) = \int_{a}^{a+\varepsilon} C \cos yx dx \sim \frac{\cos ay \,.\, \sin \varepsilon y/2}{y}$ $(\varepsilon = a/b)$;

(d) $g'(y) = \int_{a/2}^{3a/2} C \sin yx dx \simeq \frac{\cos ay/2 - \cos 3ay/2.}{y}$

There is little doubt that further technical develop-ent of the instrument will make possible the proıction of Fourier transforms with any reasonably esired accuracy. A detailed description of the new ethod will shortly be given elsewhere.

THE NEWCOMEN SOCIETY

THE jubilee dinner of the Newcomen Society held at Kettner's Restaurant, Romilly Street, W.1, n November 14, when a presentation was made to r. H. W. Dickinson, the chief guest of the evening, r his twenty-five years work for the Society, will ong be remembered by those present. It was on ovember 5, 1920, in the Court Room of H.M. Patent ffice, that the Society held its first general meeting, nd Dr. Dickinson has ever since been an honorary ecretary, except for the two years of his presidency. uring this period he has contributed many papers o the Proceedings, arranged all the summer meetings nd edited the whole of the *Transactions*, while the ontacts he made during his visits to the United tates in 1923 and 1938 had much to do with the apid growth of the Society there, a growth which as led to the formation of a North American Branch s an autonomous affiliated society with a membership xceeding five thousand.

The Society came into existence through a chance onversation between Mr. A. Titley and the late Mr. . W. Hall on September 16, 1919, at the garden party in the grounds of Heathfield Hall, held during the Birmingham commemoration of the centenary of the death of James Watt. This gathering had attracted many engineers with a love of history, and the suggestion of Mr. Titley to the effect that a society should be formed for furthering the study of the history of engineering and technology at once gained support. By May 1920 a provisional committee had been formed at Birmingham, but the Society may be said to have made its debut at a meeting a month later, on June 4, in the offices of Mr. L. St. L. Pendred, editor of the *Engineer*, at 33 Norfolk Street, London, and at a dinner held the same evening at the Savage Club, then in the Adelphi. At those gatherings Mr. Titley was chosen as president, Dr. (then Mr.) Dickinson, honorary secretary, while Messrs. Pendred, Rhys Jenkins and A. W. Hulme were to act as the London committee to collaborate with the Birmingham committee. After much discussion the question of a name for the Society was happily solved by the adoption of the surname of 'the father of the steam engine', Thomas Newcomen, of Dartmouth. Though its membership was small, the Society soon got into its stride, and at the meeting on November 5, 1920, Mr. Hulme read his paper entitled "Introduction to the Literature of Historical Engineering to the Year 1640", which forms a good starting point for any student eager to take up technological history. It appears as the first paper in vol. 1 of the *Transactions*, which contains also two of Mr. Rhys Jenkins' many papers to the Society, Mr. Pendred's "The Mystery of

Trevithick's Locomotives", a paper on "The Invention of Roller Drawing in Cotton Spinning" by the late Mr. A Seymour-Jones, and the presidential address of Mr. Titley, who dealt with the aims of the Society and the ways to achieve them.

From the first, membership of the Society has been open to all irrespective of nationality or sex, and the earliest published list contains names of members in the United States, Germany, Switzerland and China. In its second year the Society adopted an emblem, a griffin, looking backward yet going forward, and also a motto due to the late Colonel Kitson Clark, "*Actorum memores simul affectamus agenda*"; freely translated as "Mindful of what has been done, we strive at the same time after the things yet to be done". It was this idea that ran through some of the speeches at the dinner recently held, Dr. Dickinson urging the need for an influx of young and enthusiastic members to continue a work which is all the more necessary because its significance is not always appreciated.

The dinner had been preceded by the annual general meeting held at the Science Museum, when the twenty-fourth annual report of the Council and two papers were read. The report referred to the renewal of contacts with members abroad who had suffered under the Nazi tyranny, and to the formation of a Midland branch with its headquarters in Birmingham. During the War, a few meetings had to be abandoned; but all the contributions as set down in the programmes had been received and their publication in the *Transactions* only awaits the release of printers and paper. After the passing of the accounts and the re-election of Mr. S. B. Hamilton as president for a second year, a paper followed by Mr. Greville Bathe, of the United States, on "The Onandaga Salt Works of the New York State, 1646–1846". This in turn was succeeded by a review of the work of the Society during the last quarter of a century by the president. The Society, he said, had striven to achieve its objects in many ways: by enlisting the help of individuals and institutions in preserving objects of historical value, by arousing interest in local industrial history by its summer meetings, by the researches of its own members and by the publication of memoirs, by collaboration with societies having somewhat similar aims, by the compilation of bibliographies and by other means. He had classified the 358 papers contributed under the several headings of biography, ancient engineering, local industries, mills, mining, iron and steel, transport, tools, engines and the like, and he remarked that even if the Society were dissolved now, the twenty-one volumes of *Transactions* published, and the four held in suspense by inevitable delays, "are a unique contribution to historical literature". Many of the papers, he said, "are authoritative compilations by outstanding authorities who have made their respective fields peculiarly their own." As the Society has no house of its own, and meeting grounds were often chosen at places appropriate to the paper to be given, Mr. Hamilton concluded his review with an expression of thanks to the director of the Science Museum and to all those who had generously extended to the Society the use of their rooms for gatherings. In conclusion, it may be noted that besides Mr. Hamilton, the officers for the current year are Dr. H. W. Dickinson and Mr. A. Stowers, honorary joint secretaries, Mr. J. Foster Petree, honorary treasurer, with Miss G. Bingham, O.B.E., 43 King's Road, Chelsea, S.W.3, as assistant secretary.

SCIENTIFIC RESEARCH IN INDIA AND THE BRITISH COLONIES

THE first of a series of discussions on t organization of scientific research in the Briti Commonwealth, arranged by the Society for Visiti Scientists, was held at the Society's House at 5 O Burlington Street, London, on December 5, wi Prof. A. V. Hill in the chair. The speakers were Dr. S. Siddiqui, director of the Chemical Laboratori C.S.I.R., Delhi; Dr. J. L. Simonsen, director of t Colonial Products Research Council; Dr. E. Worthington, secretary of the Freshwater Biologic Association, and author of the section on "Scienc in Africa" in Lord Hailey's "African Survey" Major-General Sir John Taylor, late director of t Central Research Institute, Punjab. Those who too part in the subsequent discussion included: D W. R. Aykroyd, director of the Nutrition La oratories, Coonoor, Central India; Sir Lewis Fermo late director of the Geological Survey, India; M C. Y. Carstairs, assistant secretary at the Coloni Office; Dr. C. H. Waddington, and Dr. C. Gordon.

Among the chief points made were the following In India, government expenditure on research no amounts to the modest total of about £200,000 pe annum, but the Council of Scientific and Industri Research, which was founded in 1942, has drawn u a five-year plan for research, to be supervised by proposed new National Research Council. The tot expenditure under the plan would be £4,500,000, c which a considerable fraction would be found b industry. It would include grants for the training c a large number of urgently needed additional scientific personnel.

The outstanding results of scientific research i India to date have been in the field of tropica medicine. Here the Central Research Institute ha similar functions to the Medical Research Counc in Britain; through the Nutritional Advisory Committee, special consideration is given to nutritiona problems. The Indian Geological Survey, establishe about a century ago, is expanding its activitie notably in relation to the discovery of new minera resources and to the development of hydro-electricity

Both in India and the Colonies, nutrition is of outstanding importance. However, it has been foun that it cannot be tackled as an isolated researc problem, but requires the study of many subjects including water supply, soil erosion, malaria, agricultural science, land tenure, supply organization demography and education.

In the course of the discussion, other example emerged of problems which could only be properly tackled by this method of co-operating teams, ofte including students of both the natural and socia sciences: for example, public health and wate resources, the latter involving geology, soil-science, fisheries, meteorology, etc. The success of this method in operational research during the War was emphasized. Broad ecological research is increasingly necessary in tropical countries, and this too demands the co-operation of specialists from a number of fields.

In addition to the classical methods of research by subjects, and to this development of research and problems by wide teams, the method of research by 'sample areas' has recently been proved to be very effective. This was first tried in three different villages of Cyprus, one in the mountains, one in the foothills, one in the plains, where experts in medicine, estry, agriculture and water supply are all co-erating. This method has also been used in the lonies, and its general employment was discussed the Quebec Conference on Food and Agriculture.

One point brought out during the discussion was e disparity now existing between wealthy and poor rritories in regard to expenditure on science and applications. Thus in Malaya, the expenditure medical and health services is about 5*s*. a head of pulation, while in India, it varies from about 2*d*. 1*s*. according to district.

The need for co-operation between scientific workers the Dominions and the Colonies was stressed. Here e Empire Scientific Conference, which is to be held 1946, holds out great promise.

Another need is for the raising of the status of the ientific worker in Colonial government service, so at he can occupy the same sort of position as a search worker in a good university at home. One ay in which this could be achieved might be by ving in each territory or regional group of territories director of research, who would also be scientific lviser to the Government concerned, and to whom ientific workers in all fields should have direct access.

One of the most urgent problems in India and the olonies is the study of industrial processes which can e utilized locally. Thus the conversion of molasses to industrial alcohol could be undertaken in sugar-rowing countries, and the setting up of plants for xtracting oil from oilseeds in Africa would provide rge amounts of cattle food urgently required there. n this connexion, the decision to found a Microiological Research Station in the West Indies is of reat importance.

The discussion proved of great interest in focusing nformed opinion on the urgent problems of research n India and the Colonies.

SWEDEN'S WATER-POWER RESOURCES

DURING the War, sixty new power stations were built in Sweden, several of more than 40,000 kW. ating. The production of hydro-electric power in 944 was 12,417 million kWh., and water-power lants now total about 2,500,000 kW. Further plants otalling about 600,000 kW. will be completed towards 1950, and works have been started for an dditional 350,000 kW. The energy utilized in 1944 was 10,573 million kWh., of which 4,428 million kWh. were taken by the large industries for engine power, tc., while the electro-chemical and thermo-electric industries consumed 1,891 million kWh. About ,040 million kWh. were used for traction purposes and 2,017 million kWh. for domestic purposes, etc. ,093 million kWh. were used for electric steam-generation at night-time and during non-working hours.

Plants built during the War cost about £17,647,000, and subsequent investments amount to about £3,530,000 a year.

During 1944, plant additions amounted to 280,000 kW. Plants for a further 46,000 kW. will probably be completed before the end of 1945. Among the new power-works to be completed within the next five years or so are those at Hjälta (120,000 kW.), Forsmoforsen (75,000 kW.), and Námforsen (46,000 kW.), situated on the Ångerman River with the tributary Fax River. One station of 46,000 kW. will be built at Skedvi on the Dalalven River and one of 34,000 kW. on the Ljusnan River.

A new station at the Harsprånget waterfall in the Lule River will have a capacity of 250,000 kW. The Suorva Dam at the Stora Lulevatten, the well-lake of the Lule River, has created a water storage with a maximum capacity of 113,000 million cu. ft. and a regulating height of 19½ ft. for the new station as well as for the existing Porjus plant.

The total Swedish water-power resources which can be exploited economically is estimated to correspond to about 36,000 million kWh., of which one third has been utilized, while the second third is now being gradually taken into use. The last third will, however, be comparatively expensive to develop.

The networks of all the large power-plants are interconnected, and four heavy copper and steel-aluminium transmission lines, stretching from the north of Sweden down through the whole country, constitute the arteries through which a large part of the country's electric energy is being supplied to industries, railways and households.

NON-METALLIC DEPOSITS OF THE U.S.S.R.

A NEW publication by the Academy of Sciences of the U.S.S.R., "Non-metallic Deposits of the U.S.S.R." (published in Russian), is planned on a large and comprehensive scale. Judging by the volume at hand (Vol. 2, 1943) this publication will extend over a number of volumes and greatly exceed a similar work published in four volumes during 1926–29, as the subjects discussed in the present volume cover 449 pages as compared with 96 pages of the previous edition. Volume 2 contains the following articles, each written by a specialist or a group of specialists on the given subject: (1) basalt and diabase, (2) barite and witherite, (3) beryl, (4) turquoise ("Biruza" in Russian), (5) bitumens and bitumenous rocks, and (6) bauxite. Each section comprises the following items: general description of the material and its mode of occurrence and genesis, localities where it is found, especially those in the U.S.S.R., methods of extraction and technology, economic statistics and bibliography.

The value of this work is manifold. First, because it gives a very full account of the localities and mode of occurrence of mineral deposits, especially those found in the Soviet Union, secondly because it provides new and interesting interpretations of data, classification, genesis and novel industrial uses. Such, for example, is the article by A. S. Ginsberg on basalt and diabase (dolerite), rocks which are extremely abundant in Britain and used mainly for road-metal, while in the Soviet Union, at the present time, they are also used for manufacturing electrical insulators, acid-resisting tanks and many other articles of industrial value, in the form of the so-called 'cast basalt'. The section on bitumens, written by a group of specialists, is of exceptional interest, especially the part written by V. A. Uspensky on the genesis and genetic classification of bitumens and also that written by A. P. Vinogradov on the occurrence of certain chemical elements, such as vanadium, nickel and uranium, in bitumens. Sections describing the occurrences of bitumens in the U.S.S.R. and the technology of bituminous products are also very interesting. The prospecting for bauxitic ores in the

U.S.S.R. has been carried out on a very extensive scale during the last two decades, and the collection of articles on this subject provides a valuable summary of the results achieved as it gives detailed accounts of the various new bauxite localities of the Urals, Kazakhstan, Siberia and Central Asia.

On the whole, this publication, of which many more volumes are projected, promises to serve as an authoritative reference book to the mineral resources of the U.S.S.R.; it is of interest to geologists, miners and technologists of all countries, provided that they are familiar with the Russian language.

S. I. TOMKEIEFF.

FORTHCOMING EVENTS

Thursday, December 27

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 2.30 p.m.—Sir Robert Watson-Watt, F.R.S.: "Wireless" (Christmas Lectures adapted to a Juvenile Auditory, 1).

Friday, December 28

INSTITUTE OF WELDING, EAST SCOTLAND BRANCH (at the Heriot-Watt College, Chambers Street, Edinburgh), at 7.30 p.m.—Mr. F. Clark: "Non-Ferrous Welding".

Saturday, December 29

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 2.30 p.m.—Sir Robert Watson-Watt, F.R.S.: "Wireless" (Christmas Lectures adapted to a Juvenile Auditory, 2).

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

ENGINEERING ASSISTANTS (2) in the Borough Engineer's Department—The Town Clerk, Municipal Buildings, West Hartlepool (December 29).

LABORATORY STEWARD at the Swindon Technical Institution and Secondary School—The Director of Education, Education Office, Civic Offices, Swindon (December 29).

MECHANICAL ENGINEER (to organize and supervise the design and manufacture of machinery for use on Peat Bogs)—The Secretary, Turf Development Board, Ltd, 21 Fitzwilliam Square, Dublin (December 31).

TEACHER (full-time) OF ENGINEERING WORKSHOP PRACTICE—The Principal, Twickenham Technical College, Egerton Road, Twickenham, Middx (December 31).

ASSISTANT MASTER with qualifications in MATHEMATICS, PHYSICS, or ENGINEERING, a LECTURER IN BIOLOGY, and a LECTURER IN MECHANICAL ENGINEERING, in the Denbighshire Technical College—The Director of Education, Education Offices, Ruthin, Denbighshire (January 5).

ENGINEERING ASSISTANT, Grade E, in the Public Works Department—The Borough Engineer and Surveyor, Council House, Walsall, Staffs. (January 7).

CITY ENGINEER AND SURVEYOR—The Town Clerk, Town Clerk's Office, Bradford, endorsed "City Engineer and Surveyor" (January 8).

CIVIL ENGINEER (with special experience in Building), MECHANICAL ENGINEERS (with Works and Design experience), and MECHANICAL DRAUGHTSMEN (with Works Training and experience in Machine Design)—The Secretary, Turf Development Board, Ltd, 21 Fitzwilliam Square, Dublin (January 10).

DIRECTOR OF RESEARCH to take charge of a Research Laboratory to be set up in the Midlands for the British Sugar Corporation—The Ministry of Labour and National Service, Appointments Department, Technical and Scientific Register, Room 670, York House, Kingsway, London, W.C.2, quoting F.5532.XA (January 11).

PRINCIPAL OF THE DUNDEE TECHNICAL COLLEGE—The Clerk and Treasurer, Dundee Technical College, Bell Street, Dundee (January 12).

ASSISTANT ENGINEER—The Secretary, Burnham, Dorney and Hitcham Waterworks Company, High Street, Burnham, Bucks. (January 12).

ELECTRICAL ENGINEER AND MANAGER of the Brighouse Electricity Undertaking—The Town Clerk, Town Hall, Brighouse, endorsed 'Electrical Engineer and Manager' (January 16).

TEACHER (full-time) OF STRUCTURAL ENGINEERING SUBJECTS at the Brixton School of Building, Ferndale Road, London, S W.4—The Education Officer (T.1), County Hall, London, S.E.1 (January 16).

TEACHERS (full-time) OF MECHANICAL ENGINEERING SUBJECTS at the South-East London Technical Institute, Lewisham Way, London, S E 4—The Education Officer (T.1), County Hall, London, S.E.1 (January 18).

PRINCIPAL OF THE COUNTY TECHNICAL COLLEGE, Dartford, and REGIONAL PRINCIPAL FOR TECHNICAL EDUCATION in the area served by the College—County Education Officer, Kent Education Committee, Springfield, Maidstone (January 23).

PHYSICAL CHEMISTS or PHYSICISTS in connexion with development of Plastics—The Ministry of Labour and National Service, Appointments Department, Technical and Scientific Register, Room 670, York House, Kingsway, London, W.C 2, quoting F.5261.XA (January 25).

LECTURER IN MECHANICAL ENGINEERING (Ref. No. C.2931.A), LECTURER IN ELECTRICAL ENGINEERING (Ref No. D.1557.A), LECTURER IN WIRELESS ENGINEERING (Ref No. D 1558.A), LECTURER in INSTRUMENTS TECHNOLOGY (Mechanical) (Ref. N C.2978.A), and a LECTURER IN INSTRUMENTS TECHNOLOGY (Optic (Ref. No. C 2979.A), under the Military College of Science, Stoke-c Trent—The Ministry of Labour and National Service, Appointmen Department, Technical and Scientific Register, Room 670, Yo House, Kingsway, London, W.C 2, quoting the appropriate Ref. N (January 26)

ILLUMINATION ENGINEER to undertake development work on t application of plastics in the lighting field—The Ministry of Labour a National Service, Appointments Department, Technical and Scienti Register, Room 670, York House, Kingsway, London, W.C.2, quoti D.1629 XA (January 28).

SECRETARY TO THE MEDICAL SCHOOL—The Dean, St. Thomas Hospital Medical School, London, S.E.1 (January 31)

PHYSICAL CHEMIST to evolve polarographic and other metho suitable for the analysis of plants and supervise their routine, u and a PHYSICIST to evolve spectrographic and other methods suitab for the analysis of plants and supervise their routine use—The Secr tary, East Malling Research Station, East Malling, Maidstone, Ke (January 31).

LECTURER IN CHEMICAL ENGINEERING in the Department of O Engineering and Refining—The Secretary, The University, Edmun Street, Birmingham 3 (February 1).

LECTURER IN THE DEPARTMENT OF LEATHER INDUSTRIES—T Registrar, The University, Leeds 2 (February 28).

LECTURER IN PHYSIOLOGY—The Secretary, Queen's Universit Belfast (March 31).

REGIONAL DIRECTOR (West of Scotland) and DIRECTOR OF CENTRA DEPOT (Western Area) at Glasgow (joint appointment), and a REGIONA DIRECTOR (South-East Scotland) and DIRECTOR of CENTRAL DEP (Eastern Area) (embodying Plasma Drying Unit) at Edinburgh (joi appointment)—The Secretary, Scottish National Blood Transfusi Association, 10 Duke Street, Edinburgh 1 (April 20).

PROFESSOR OF PHYSICS—The Principal, Heriot-Watt Colleg Edinburgh (April 22).

TECHNICAL ASSISTANT (Hæmatology) (non-resident, male or femal for Clinical Laboratory Work—The General Superintendent an Secretary, Royal Infirmary, Manchester.

ASSISTANT PHYSICIST in the Radiotherapy Department—The Hou Governor, London Hospital, Mile End, London, E.1.

PROFESSOR OF PHYSIOLOGY in the University of Ceylon—Th Secretary, Universities Bureau of the British Empire, c/o Universit College, Gower Street, London, W C.1.

LECTURER IN MATHEMATICS in the Natal University Colleg Pietermaritzburg—The Secretary, Universities Bureau of the Britis Empire, c/o University College, Gower Street, London, W.C.1.

CURATOR-LIBRARIAN (experienced) by an Oil Company in Ira to take charge of literature and fossil collections in geological lab oratory—The Ministry of Labour and National Service, Londo Appointments Office, 1-6 Tavistock Square, London, W.C.1, quoti F.A.158.

BIOCHEMIST or CHEMICAL ANALYST (graduate, experienced), an HOSPITAL or LABORATORY TECHNICIANS, for work with nutrition team in Germany—The Director, Oxford Nutrition Survey, 10 Park Road, Oxford.

LECTURER (full-time) IN AUTOMOBILE ENGINEERING for Day an Evening work—The Principal, Leicester College of Technology an Commerce, The Newarke, Leicester.

RESEARCH ASSOCIATE—The Secretary, National Institute of Economic and Social Research, 53 Romney Street, London, S.W.1.

PENICILLIN: A STUDY IN CO-OPERATION

MUCH has recently been heard of co-operation between scientific workers of Great Britain and of the United States in physical research, and the successful outcome of the work which culminated in the production of the atomic bomb has been widely quoted as an indication of the value of such co-operative effort and the desirability of its continuation in the future. With the publication of the statement on the chemistry of penicillin which appears in this issue of *Nature* (p. 766), there is revealed the existence of another co-operative effort in research, directed towards a very different end. This publication may serve to correct the general but mistaken impression that scientific work during the War has been mainly concerned with the destruction of man. It is of some interest to consider the background against which this extensive collaboration in work on penicillin was developed and the implications which it carries for the future.

As soon as the potential importance of penicillin as a therapeutic agent had been demonstrated by Florey and his collaborators, intensive chemical work on the substance was initiated in Florey's own laboratory and in the Department of Chemistry at Oxford. From the time of the formation in 1942, at the instance of the Ministry of Supply, of the General Penicillin Committee, which was charged with the duty of doing everything possible to increase production of penicillin, other academic and industrial laboratories in Great Britain were drawn into the work and a considerable measure of co-operation was achieved in this country.

As the work on the constitution of penicillin proceeded, and as the formidable difficulties of large-scale microbiological production of the substance were realized, the question of the development of a synthesis acquired considerable urgency, and through the Medical Research Council steps were taken to make the collaboration between British chemists engaged on the problem more intimate and effective. For this purpose the Council set up a Penicillin Synthesis Committee (under the chairmanship of Sir Robert Robinson, Waynflete professor of chemistry in the University of Oxford), which included distinguished chemists from both academic and industrial organizations working on this subject. By this time it had become apparent that, owing to the difficult situation in Great Britain, and to the greater resources of labour, material and technical knowledge of microbiological methods in the United States, it was from America that really large-scale microbiological production of penicillin was first to be anticipated. That this anticipation has been realized is now a matter of common knowledge; what could not be foreseen at the time was that the most hopeful expectations would be far exceeded by an effort in the industrial application of microbiology which is probably without parallel in the past.

The development of the national effort in the microbiological production of penicillin in the United States naturally involved American chemists in work similar to that which had already been begun in Great Britain on the constitution of penicillin with a view to its subsequent synthesis. The potentialities of penicillin not only in matters affecting the health of the civil population but also in directly assisting military operations by controlling infection of wounds, and thus reducing disability, were fully realized both in Britain and in the United States ; this realization brought the recognition that work directed towards synthesis, which at that time seemed to offer the best prospect of the rapid production of the substance in large quantities, was a matter of the greatest importance to both countries.

Since this conviction was shared on both sides of the Atlantic, it was possible for the Medical Research Council to arrange with the Office of Scientific Research and Development in Washington, which itself was co-ordinating American work on penicillin on behalf of the United States Government, for the complete and up-to-date exchange between the two countries of all research information bearing on the synthesis of penicillin. Thus, the Penicillin Synthesis Committee of the Medical Research Council referred to above became a co-ordinating centre in Britain not only for all British research on the constitution and synthesis of penicillin but also for the complete Anglo-American collaborative effort. The statement which is now published gives an outline of the unequivocal results obtained in Britain and in the United States both before and during the operation of this collaborative arrangement, up to the middle of 1944.

Full assessment of the value of the chemical work which has resulted from the international co-ordination of research on this subject must naturally await the complete publication of the results, which it is hoped may not be long delayed. In the meantime, however, the impressive amount of this work is immediately apparent from the preliminary statement, which also brings to light other facts of interest. The first is the extraordinary and unexpected difficulty of the problem. The molecule of penicillin is not large, and, as the statement indicates, the general features of its structure are revealed by identification of the products of acid hydrolysis ; on the other hand, some of the transformations undergone by penicillin are not easy to explain and it is clear that there has been difficulty in reaching finality about its constitution. A measure of the magnitude of the problem is afforded by perusal of the list of groups both in Britain and in the United States which have participated in the work, and this list is itself a second matter of interest to which attention may be directed. Not only have some of the most distinguished organic chemists in both countries directed their efforts to the problem, but also every potentially useful phys.co-chemical and physical technique has been brought to bear on it. Never before indeed can there have been such a concentrated attack on the chemistry of a single compound. It seems that penicillin is almost as remarkable in the tenacity with which it holds the secrets of its molecular structure as it is in the biological properties which give it its peculiar importance.

Whether or not we are ultimately to learn that t collaborative research on penicillin has led to succe the announcement that such a collaboration has be possible at all is an event of considerable significanc A few years ago it would have been quite inconceivab that a project with such possibilities of commerc development could have been the subject of pool research, involving a completely free interchange information, between a group of organizations suc as those listed at the end of the statement ; this li includes, for both Britain and the United State academic laboratories, government research institu tions and the research departments of industrial fir which are normally commercial competitors. Tho who have knowledge of the working of the arrang ment are aware of, and have been impressed by, th complete loyalty with which all participants hav observed the conditions of co-operation.

Even if it be admitted that such a collaboratio in research on a subject of potential commerci value could only have been arranged under th special conditions prevailing in war-time, when th motive of commercial competition is submerged b that of defence of the country, the evident succes of the temporary arrangement is certainly a goo omen for the future. It becomes increasingly clea that for the advance of science in any country particularly perhaps for the advance of chemistr and physics, a closer co-ordination is desirable tha has hitherto existed between the research work whic is done in universities, government institutions an industrial laboratories. Of the difficulties whic have stood in the way of such co-ordination in th past, the greatest is probably the inevitable diffe ence of outlook induced by the necessities of com mercial practice. This has tended to set up a barrie between the academic research worker whose trad tions demand free publication of all results and fre interchange of information with his scientific col leagues, and the industrial research worker whos first duty is to the interests of his own firm. With th resumption in peace-time of normal commercia practice, this difficulty will necessarily reappear an it is useless to minimize its seriousness. Nevertheless even the temporary breakdown of the barrier by a collaborative arrangement such as has operate during the last few years in the field of penicilli chemistry can scarcely fail to exercise a lasting effec for the good. On one hand, the academic participants will have had an opportunity, such as coul not otherwise have been afforded to them, of learning something of the quality of research work which is carried out in industrial organizations, and they will certainly thereby have acquired a greater respect for this work ; on the other hand, it may be hoped that the industrial research workers may have become more impressed than they formerly were with the very real benefits which may be derived in scientific work from free consultation and discussion with colleagues. If such a conviction were established, it would probably also result in a change of policy in the direction of prompt and complete publication of scientific results from industrial research laboratories to the maximum extent consistent with adequate tection for development; no move could be more ourable to the recruitment of able scientific rkers to industry than an increase in the oppor- ities afforded to them for publication and, ough this, for the development of a scientific eer.

f the collaborative research on penicillin has been ective in starting a move in the directions indicated, s may ultimately be counted a contribution to the vancement of science as important as the actual entific work for which the collaborating parties ve been responsible.

SCIENCE AND MYSTICISM

e Physical Basis of Personality

Prof. V. H. Mottram. (Pelican Books, A.139.) . 126. (Harmondsworth and New York: Penguin oks, Ltd., 1944.) 9*d*.

N this book the reader will find a stimulating discussion of known facts about heredity, genes, docrine organs and related biological conceptions. e terminology of these conceptions is freely used wadays, often without a clear understanding of its eaning. It is therefore important that this meaning ould be precisely understood. For this reason alone is book should be read.

Apart from this point, however, the book is worth ading for the sake of its last chapter entitled Recapitulation and Coda". If some readers reject e author's criticism of the determinist materialist ilosophy which is so popular nowadays (again often ithout adequate understanding of its full implicaons), others will welcome the method which the thor adopts of avoiding the pessimism and unppiness which materialism so often brings. The ay indicated is a mysticism reconciled with scientific scovery. It will not be everyone's way of meeting e philosophical challenges of science. At least one ther way is available, namely, the lonely way exounded by Sir Charles Sherrington in his "Man on s Nature", which book Prof. Mottram highly comends. Commendable Sir Charles Sherrington's book ost certainly is, in spite of its difficult style; but counsels a solution which the mystic could not dopt. For Sherrington there can be no leaning for ounsel and guidance upon a higher mind or personaly. Man must shoulder his burden alone; and by cceptance of that "loftier responsibility", he is aised, in Sherrington's opinion, to "a rank of obligaion and pathos which neither Moses in his law-giving or Job in all his suffering could present".

This attitude, admirable though it is, requires for s acceptance a mind too subservient to logic and the cientific method to be representative of the newest evelopments of human intelligence. Much recent riting indicates this. To mention only one example, r. Clark-Kennedy, in his lecture on "The Art of edicine in Relation to the Progress of Thought" Cambridge University Press, 1945), has ably set out ome of the reasons why science is not enough for he proper practice of the art and science of medicine. Mottram, in the book under consideration, and the thers, ancient and modern, whose work he quotes, emind us of an experience less tragic, if no less ifficult, than that indicated by Sir Charles Sherringon—an experience which has been variously called communion with an inner spirit or reality, the quest of the world-soul, submission to the absolute (which does not, be it noted, necessarily involve acceptance or even understanding of Hegelian philosophy), the search for the spirit of the whole or accordance with the inner necessity. Yet others, like McTaggart and Younghusband, have frankly and simply called it love. It is an experience which all of us may have if we will; we may have it, too, without any very esoteric disciplines. Most men of science, in any event, will probably be able, if they are honest with themselves, to apply to their own experience Sir Olaf Stapledon's description, quoted by Mottram from Stapledon's "Saints and Revolutionaries", of that "very comprehensive act of attention, an attending to everything at once, or to the wholeness of everything at once" which brought to Stapledon "a tension of fervour and peace" and might easily, he goes on to say, be regarded, if he were less sceptical, as some kind of contact with God.

One way of experiencing this kind of emotion—and of doing so without necessarily excluding God—is to watch, in the circle of green light beneath a microscope, the ways, say, of the trypanosome which can, and inevitably will, if conditions are favourable, kill a Christ and a Hitler alike. The proper understanding of the conditions necessary for this entirely inhuman and amoral act requires an intellectual discipline, maintained for many years of close and exacting study, which the orthodox mystic can scarcely comprehend. The mere act of looking down a microscope will not provide it, though the microscope can, like the rites prescribed by orthodox mysticism, shut out the disturbances of the immediate surroundings and focus the attention. It can focus the attention, moreover, upon those small details which, both by their cumulative effects and their individual significance, reveal to the experienced mind a good deal which the philosopher, who looks at the landscapes of science rather than at their several components, cannot possibly apprehend. It can focus the attention, in addition, upon those minute inexactitudes which at once justify the disciplines of the scientific method and at the same time reveal its limitations. It can endow the observer with a "snail-horn delicacy of perception" which is essential to any effort towards the understanding of those wider landscapes which the philosopher seeks to delineate.

The remainder of the mystic procedure will come naturally to the man of science. The elimination of the self, so far as this is possible to the Adam in us, is habitual to the scientific worker, who cannot, unless he achieve some considerable measure of it, begin to work at all. To him also comes naturally that deep and essentially religious awareness of abstract beauty, which goes so far beyond the appreciation of beauty of form—the realization, in other words, of the difficult beauty of adaptation, evolution, development and obedience to natural law. The slow and inspiring growth in the mind of all that this kind of beauty implies comes only, during the years, from the disciplines of study, disappointment and refusal to escape into easier ways; and these are disciplines as difficult as any that the orthodox mystics have enjoined. When knowledge is thus gained in any field of scientific work, and is related, as only the experienced man of science can relate it, to the same kind of knowledge won from the similar study of other aspects of the universe, then the mind experiences, in rare moments of synoptic insight, a reverent and exhilarating certainty of the essential unity of all phenomena appreciable by the mind, and of the omnipresence of an inner reality pervading all, which inspires and pervades the whole life and character of him who experiences it. It is this that equates the amœba with him who has thought his apprehension like a god's; it is this which has created, out of truth and beauty, the atomic bomb which awaits man's dedication of it, in action and not merely in a form of words, to the service of the good; it is the germ of this which Prof. Mottram offers to those who read his book.

For this reason, if for no other, this book can be commended to all those who are seeking at this moment—and desperately seeking—some reintegration of that belief in the existence and even in the good purpose of an inner reality which the recent War, and the evil of those who instigated it, may seem to have shattered beyond recovery. It shows beautifully the moral worth of the service of the truth. Read sincerely and with imagination, it spans the ages of man's experience. With the terrible charity which modern truth must exercise, it links the modern microscope with "the eye of my soul" which beheld, "above my mind, the Light Unchangeable".

G. LAPAGE.

A GREAT PHYSIOLOGIST

Léon Fredericq et les débuts de la physiologie en Belgique

Par Prof. Marcel Florkin. (Collection Nationale, Troisième Série, No. 36.) Pp. 104. (Bruxelles: J. Lebègue et Cie., 1943.) n.p.

PHYSIOLOGISTS the world over, and especially in Belgium, have reason to be proud of Léon Fredericq. Born in 1851, he became an outstanding figure in the classical period of physiology. Between 1870 and 1880, the institutes of physiology for the promotion of teaching and the encouragement of research, which came into being in various countries, necessitated the creation of whole-time chairs of physiology. In Belgium such innovations were encouraged by the State, and Léon Fredericq was appointed to the chair at Liège in 1879 in succession to Théodore Schwann, and charged with the creation of a new Institute of Physiology, which was completed in 1888. In the forty-two years during which he directed the Institute, it made history, and on reading this elegant little essay, one realizes why so high a place in world physiology is held by so small a country.

Fredericq's knowledge was encyclopædic, his experience wide and his talents manifold. Among the latter was high ability as a popular lecturer and as a water colourist. A great naturalist, we owe much to his researches in the comparative field, his most memorable discovery being that of hæmocyanin.

His contacts were closest with France and Germany, and though he had many friends in Britain too, his work was less well known here than it should have been. It is not generally known, for example, that he invented an apparatus, the oxygénographe, applicable for use on man, for reading off oxygen utilization, and recognized by Benedict as a prototype of the arrangement which he so extensively used. He was the initiator of the technique of crossed circulation, and his work on the respiratory exchange as reveal by tonometric determinations, on the left auricu pulsations as studied by œsophageal sounds, and the time relations of events in the cardiac cycle, widely known. Much of his work was biochemi and included investigations on blood coagulatio in the course of these he recognized the three ma proteins of the plasma.

The book is full of interest, and is a valua contribution to the history of physiology, wi thoroughly painstaking bibliography and footnot

C. LOVATT EVANS.

ACCOUNTING FOR FARMERS

Good Farm Accounting

By A. C. Campbell. (Teach Yourself Farming Serie Pp. 200. (Bickley: English Universities Pres Ltd., 1945.) 3*s*. 6*d*. net.

IF there is one branch of farming that can be lear from books it must certainly be book-keepin Formerly farmers were inclined to regard accoun as an unnecessary encumbrance in a life mostl spent in field and market; but recent changes taxation have compelled practically all of them provide statements of their affairs that will satisf the Inland Revenue authorities.

If we must have accounts, however, let us hav them in such a form as to give the maximum amoun of information about the running of the busines with the minimum of effort.

The author, who has had an extensive and varie farming experience, assumes no previous knowledg of bookkeeping on the part of his readers. Startin from first principles, he leads on through a serie of farm accounts posted by double entry, the example increasing in scope as the more intricate points ar illustrated. Thus the treatment of the farmer' personal expenses, produce consumed in the farm house and payments in kind to farm workers, ar discussed at some length. The interpretation o balance sheet and profit and loss account as a guid to management also receives attention.

For those who desire to keep their accounts i the simplest form consistent with accuracy an efficiency, the author proceeds to describe the single entry system using an account book of his own desig as an illustration.

A section on cost accounting follows. The autho shows how cost accounts give a clearer view of the situation in the various farm departments than the purely financial treatment can provide. Further, when handled in mass by experts, they can form a basis for moulding agricultural policy. The nature of the records necessary to build up these accounts is explained with illustrations of the appropriate forms, but it is admitted that the procedure is too exacting for most farmers whose business is not big enough to justify the employment of a clerk.

Information relating to business methods and procedure forms an important part of the book. Certain tables of weights and measures, and valuers scales of compensation are given, some of which might with advantage have been included in an appendix.

The financial accounts are presented in sufficient detail to be readily followed by a beginner.

e Molluscan Family Planorbidæ

Frank Collins Baker. Collation, revision and ditions by Harley Jones van Cleave. Pp. xxxvi+ 0 (141 plates). (Urbana, Ill.: University of inois Press, 1945.)

HIS important monograph, based on exhaustive anatomical research, was nearing completion at e time of the author's death in May 1942; the llation, revision and additions necessary before blication having been carried out by H. J. van eave.

Frank Collins Baker's researches on the anatomy d ecology of North American freshwater Pulmonata ve long been familiar to malacologists on both les of the Atlantic, and valued for their accuracy d originality of concept; while the publication ore than thirty years ago of his monograph on the ymnæidæ of North and Middle America established s reputation as one of the few authorities on the bject. The present work, to which he devoted uch time and labour during the last twenty-five ars of his life, will long remain not only a lasting emorial to the man and his work, but also a andard text-book and work of reference. It fully nfirms the importance of a study of the compara- ve anatomy of the soft parts of these molluscs as ving the only true key to a natural classification, r the shell cannot be relied upon entirely for this urpose, its characteristics often proving misleading n account of the presence of many cases of parallel evelopment. That certain features of shell morpho- gy, however, when used in conjunction with the natomical details of the body, are of importance in stablishing a satisfactory classification of the lanorbidæ is fully demonstrated both in the text nd by the many admirable illustrations.

In the compilation of the work, the author had xamined no fewer than 725 specimens representative f eighty-one species and races of the family; the umber of species examined being divided among ne four subfamilies as follows: Planorbinæ 19; egmentininæ 11; Helisomatinæ 41; and Planor- ulinæ 10. The wide geographical distribution of ne Planorbidæ and their economic significance as the ntermediate hosts of various disease-producing arasitic trematodes renders the intensive study of hese freshwater molluscs one of prime importance, nd one to which the work under review forms a aluable and authoritative contribution.

F. MARTIN DUNCAN.

he Economics of Advertising

y F. P. Bishop. Pp. 200. (London: Robert Hale, td., 1944.) 7*s*. 6*d*. net.

A GOOD general dictionary tells you that advertising simply means making a thing widely nown by circular, etc., but a scrupulously careful cientific handbook tells you that advertising means 'the process of notifying *or persuading* people without ersonal solicitation" (italics ours). The difference etween the two statements makes all the difference —notifying, yes, by all means; persuading, a much more hesitant yes. The kind of thing that bothers most eople about advertising, is the patent-medicine dvertisement that blurs the distinction between alliatives and cures, the advertisement for pills that ulgarly disfigures a lovely landscape, the window-dressing that induces people to buy what they do not need and cannot afford. Evidently advertising ouches psychology, ethics and æsthetics as well as economics. Of all this the author of this fine book is perfectly well aware. He promises to deal later on with "the various ethical and social problems raised by the practice of commercial advertising". In this volume he adheres to his purpose as indicated in the title. The book is packed with information and suggestions coming from one who is obviously master of his subject, who has lived it as well as studied it, and who helps the reader to form a judgment as to the immediate future of advertising.

Waveform Analysis

A Guide to the Interpretation of Periodic Waves, including Vibration Records. By R. G. Manley. Pp. xi+275+3 plates. (London: Chapman and Hall, Ltd., 1945.) 21*s*. net.

THE development of high-speed mechanical engines and similar devices has, during the last decade, brought forth a demand for both recording vibration amplitudes with accuracy and the analysis of such wave-forms as are thus obtained. The present author, while indicating methods of recording, is largely concerned with analysis, which is rendered complicated by the fact of frequencies which are not exact multiples. It is therefore necessary to extract beats and to endeavour to relate them to various other frequency components which are inherent in the wave-form. The precise analysis of the frequencies is essential in order that the source of the vibration component may be traced. It is important, therefore, that an exact record is taken simultaneously of any fundamental frequency of rotation in the machines being tested; but the author shows that variations in the actual speed of the record can be tolerated, provided this extra recording, as well as the time-scale, is also made. The author is to be congratulated on the completeness of his practical treatment, and the advice he has to give in interpretation; in particular, mechanical analysers are dealt with, especially that one devised by J. Harvey.

L. E. C. HUGHES.

Witchcraft in England

By Christina Hole. Pp. 168+16 plates. (London: B. T. Batsford, Ltd., 1945.) 21*s*. net.

THIS is an industrious and careful study of the voluminous records of various kinds of witchcraft and kindred practices, some of which survive to-day. The bibliography would have been more useful if dates of publication had been given throughout. The preliminary chapter on the "Art of Magic" follows Sir James Frazer's view that magic is "probably older than religion"; but doubt is cast on Miss Margaret Murray's belief in a "Witch Cult in Western Europe" transmitted from pagan times, though many rites and beliefs are of pre-Christian origin. The various forms of harmful magic are classified and illustrated in detail, with the ingenious and horrible methods of detecting witches within historic times, and the comparatively harmless practices of the 'white witch', which have survived the repeal of the statute against witchcraft in 1736 and the spasmodic panics, here and there, of later date.

As very few references are given, the result of so much labour is of no scientific value; and the more-than-Hogarthian illustrations by Merwyn Peake appear to be works of imagination. Only one has a place-name, but the church of Walton-in-le-dale does not look like that.

J. L. M.

CHEMISTRY OF PENICILLIN

THIS brief summary of results obtained by British and American chemists, issued under the joint auspices of the Committee on Medical Research (Office of Scientific Research and Development, Washington) and the Medical Research Council (London), is a preliminary notice of the principal findings secured up to the end of 1944 in a collaborative effort of a large number of investigators, unnamed at present. It implies some corrections of published data; authors of early publications are among those who have cleared up these points. For the sake of clearness, the account is not given in chronological order of development. The primary object of this communication is to disclose significant facts which have been confirmed by unequivocal synthesis and to record a few essential points which are still matter for conjecture. Full details will be disclosed at a later stage, together with an account of experiments not referred to in this report.

Several antibiotics of the penicillin class are known and all have the empirical formula $C_9H_{11}O_4SN_2R$. In penicillin-I (known in America as *F*-penicillin), R is Δ^2-pentenyl, $—CH_2.CH{=}CH.CH_2.CH_3$; in dihydropenicillin-I, R is *n*-amyl; in penicillin-II (known in America as *G*-penicillin), R is benzyl; in penicillin-III (also known as *X*-penicillin), R is *p*-hydroxybenzyl. In *K*-penicillin (a recent addition to the series) R is *n*-heptyl. The best elementary analyses are of pure crystalline sodium salts. Determinations of the molecular weights of the sodium salt and of the methyl ester of penicillin-II indicate that the empirical formulæ truly represent the molecular weights.

The penicillins are strong monobasic acids of pK about 2·8; electrometric titration does not disclose the presence of a basic group. Slow titration with perchloric acid in acetic acid solution indicates such a group, but the penicillin is biologically inactivated by this treatment; rapid titration gives a negative result.

The ultra-violet and infra-red absorptions, crystal structure (by X-ray methods including full electron distribution of the rubidium salt of penicillin-II), and polarimetric and polarographic behaviour of the penicillins and their derivatives have been studied.

Sodium penicillin-II contains one hydrogen atom replaceable by deuterium on equilibration with heavy water.

On treatment with hot dilute mineral acids the penicillins afford one molecule of carbon dioxide, an amino-acid termed penicillamine and other products. Penicillamine, obtainable by several other degradation processes, has been identified by analytic and synthetic methods as *d*-β,β-dimethylcysteine. Penicillamine with the same steric configuration is derived from penicillins-I and -II; it belongs to the *d*- or 'unnatural' series of α-amino-acids.

Synthetic penicillamine has been resolved and numerous derivatives of the optically active enantiomorphs and the racemic form have been prepared. These include penicillamine disulphide (tetramethylcystine) and penicillaminic acid (dimethylcysteic acid) as well as a long series of thiazolidines, and S- and N-substituted derivatives.

After removal of penicillamine from the acid hydrolysates, careful treatment of penicillin-I allowed of the isolation of an aldehyde, $C_8H_{13}O_2N$, in the form of its 2:4-dinitrophenylhydrazone and its condensation product with dimedone. Si ilarly, dihydropenicillin-I gave rise to derivati of an aldehyde, $C_8H_{15}O_2N$. Penicillin-II afford phenaceturic acid, phenylacetamide and an alc hyde, $C_{10}H_{11}O_2N$. Phenylacetic acid had pr viously been recognized as a hydrolytic product penicillin-II.

These *penillo-aldehydes* have been identified analysis and synthesis as follows: penillo-aldehyde- Δ^2-hexenoylaminoacetaldehyde; dihydropenillo- dehyde-I, *n*-hexoylaminoacetaldehyde; penillo-ald hyde-II, phenylacetylaminoacetaldehyde.

It was inherently probable that the carbon dioxi liberated when penicillin is hydrolysed in hot ac solution was derived from an unstable carboxyl grou and, taking into consideration the nature of penici amine and the penillo-aldehydes, a probable pr cursor was penillo-aldehyde-carboxylic acid, CHO.C (CO_2H).NH.COR, now termed a *penaldic acid*. Th was conclusively demonstrated to be correct.

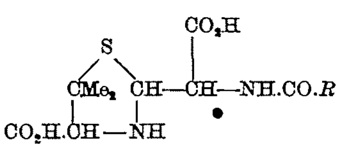
Penicillin-II and benzylamine afford a crystalli compound, $C_{30}H_{36}O_4N_4S.H_2O$, which has the con position of a hydrated addition compound of o molecule of penicillin-II and two molecules of benzy amine and is the mono-benzylamine salt of the mon benzylamide of a dicarboxylic acid. Degradation this substance by means of mercuric chloride afforde penicillamine and penaldic-II acid benzylamide whic was catalytically reduced to hexahydrophenylacety serine hexahydrobenzylamide, $C_6H_{11}.CH_2.CO.NH$ $CH(CH_2OH).CO.NH.C_7H_{13}$, identified with a syn thetic specimen.

The penicillins are readily inactivated by methan and the products are methyl esters. Methanol inactivated penicillin-II was degraded to methyl penaldate-II, $CHO.CH(CO_2Me).NH.CO.CH_2Ph$, th constitution of which was proved by its catalyti reduction to N-hexahydrophenylacetylalanine The latter was identical with a specimen prepare by similar reduction of phenylacetylalanine. Penicillins-I and -II are converted by the action of diazomethane into mono-methyl esters and these are degraded by mercuric chloride in aqueous solution wit formation of the methyl ester of penicillamine.

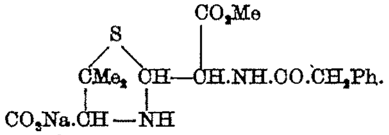
These observations serve to show (1) that the acidi group in penicillin is identical with the carboxy group in penicillamine, (2) that by the addition o the elements of water to penicillin a second carboxy group is produced, (3) that it is this new carboxy which breaks down to carbon dioxide by the actio of hot dilute mineral acids.

The dicarboxylic acid obtained by hydrolysis o penicillin at the site of the potential carboxyl i termed *penicilloic acid*. This acid is produced in the form of salts by treatment of penicillin with alkalis, and is presumably the product of the action of the enzyme penicillinase on penicillin.

Derivatives of penicilloic acid have been synthesized and the outcome of much work that cannot here be described in detail is that penicilloic acids are undoubtedly thiazolidines of the formula:



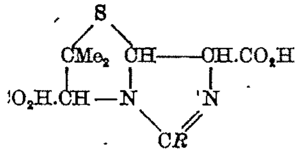
Where R is one of the groups already particularized. hus 'methanol inactivated' sodium penicillin-II is ne of the stereoisomeric forms of the structure:



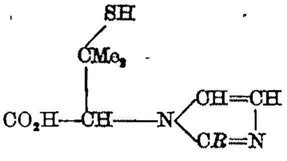
When any of the penicillins is held in dilute mineral cid solution at about 30°, a change occurs which may be followed polarimetrically. Crystalline isomerides of the penicillins termed *penillic acids* may then e readily isolated. These substances are shown by ectrometric titrations to be dibasic acids containing basic group: thiol groups are absent.

Treatment of the penillic acids with cold aqueous mercuric chloride involves loss of a molecule of arbon dioxide and formation of substances termed *enillamines*. These compounds are monobasic, mono-acidic and contain a thiol group.

Analysis and synthesis have shown that the annexed xpressions represent the respective structures

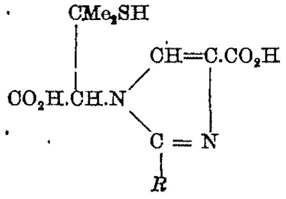


Penillic acids



Penillamines

Penillic-I and -II acids are convertible by baryta into the isomeric *iso*penillic acids.



*Iso*penillic acids

Hydrolysis of the penillic acids by hot dilute acids affords penicillamine, the penillo-aldehydes and carbon dioxide; but the penillamines are resistant to hydrolysis.

Methyl penicillin-II is changed by mercuric chloride n neutral media into the isomeric methyl penicillenate-II which, on hydrolysis by means of aqueous sodium hydroxide, affords the sodium salt of 4-hydroxymethylene-2-benzyloxazolone. The addition of the elements of thiocyanic acid to methyl penicillin, and the transformations of the primary product have been investigated in detail with important results.

Finally, the action of Raney nickel catalyst on sodium penicillin-II in aqueous solution affords desthio-penicillin-II, $C_{16}H_{20}O_4N_2$, together with phenacetyl-*l*-alanyl-*d*-valine, $C_{16}H_{22}O_4N_2$.

Naturally the workers in this field have formed views as to the full constitution of the penicillins. At present it can be stated that the formulæ which are now receiving the most active attention contain respectively a β-lactam structure (I) and an incipient azlactone grouping (II):

AMERICAN WORK ON THE ATOMIC BOMB PROJECT

JUST as soon as it was discovered that secondary neutrons are liberated in uranium fission to the extent of considerably more than one for each heavy nucleus transformed, and that types of nuclei exist which undergo fission under bombardment with neutrons of all energies, it became a reasonable scientific guess that the attainment of a self-propagating (divergent) nuclear chain-reaction would eventually prove possible. So much was, in fact, commonly known by physicists in the late summer of 1939—and the implications of this knowledge in relation to the likely development of military weapons of extreme power were not altogether unheeded by scientific men whose countries were very obviously slipping helplessly into war. In the United States, also, attempts to arouse official interest in the new possibilities were not entirely without effect. By slow degrees this latter interest quickened, and a few weeks before the Japanese attack on Pearl Harbour, American service chiefs were ready to sanction a greatly intensified effort on the problem. Early in 1942 a full-scale research and development programme was under way and plans for pilot production plants were in hand. Almost exactly three years later, what had appeared in sober estimate so distant was an actuality; the first bomb had not been dropped, but the scientific workers in charge of the project were satisfied that success was well-nigh inevitable, and large production plants were rapidly accumulating the fissile material which it was planned to use.

As is well known, the crucial trial was not staged until mid-July 1945—and it was not until August 6 that the new weapon was used offensively; but earlier in the year the scientists' efforts had progressed so far that some of them at least were able to relax a little and look beyond immediate problems of physical research to the impact which the employment of the weapon would be certain to have on the world at large. The heads of the Allied States concerned in the development of the bomb would obviously find it necessary to issue statements setting out briefly what had been done and indicating their policy towards the enemy if he remained unsubmissive; but it was felt that the peoples of the Allied Nations could not be left without further information, and that a popular exposition was needed which would allow them to appreciate the magnitude of the scientific achievement involved and—always within the limits imposed by considerations of security—permit them to look into the future with some guidance in their certain bewilderment.

The American scientists who acted on these conclusions are to be congratulated on the results of their efforts, first in obtaining the support of the military authorities in whose hands the question of security was vested, and secondly on the popular account itself which has been issued by the Government Printing Office in Washington* (and has also been reprinted and published by H.M. Stationery Office in Great Britain†), having been compiled by Prof. H. D. Smyth, chairman of the Department Physics of Princeton University. This documen which was authorized for issue in America in Augus very soon after the attack on Hiroshima, runs t 182 pages. The author's preface is dated July 1945. The style is reasonably unhurried throughout the whole thing cannot have been written overnigh It is to be repeated that the foresight which con ceived the aim and scale of the report, and which le to its production, is greatly to be commended. I Great Britain we had less in the way of large-scal achievement to report upon, but it will be recalle that we also produced a 'popular' account for issue i August. The American account should be considere in one aspect, at least, in relation to the British on —to the necessarily incomplete but otherwise quit admirable White Paper* published by the Stationer Office. This is said in no spirit of criticism: it reflect merely the statement in Prof. Smyth's preface "References to British and Canadian work are no intended to be complete since this is written from the point of view of the activities in this country"

The American report is divided into thirteen chapters each with a summary, and there are fiv appendixes. The first chapter (twenty pages) and th first two appendixes ("Methods of Observing Fas Particles from Nuclear Reactions" and "The Unit of Mass, Charge and Energy") provide a backgroun of knowledge of fundamental nuclear physics t supplement the general scientific outlook which th reader of the report is assumed to possess—"[It] i written for this professional group . . . of engineer and scientific men who can understand such thing and who can explain the potentialities of atomic bombs to their fellow citizens". Chapters 2–5 giv the administrative history of the project in its various stages, Chapter 6 describes in general term the research carried out at Chicago in 1942, and Chapters 7 and 8 and 9 to 11, respectively, trace the development of the production methods used for plutonium 239 and uranium 235, the two fissile materials used for the bombs. The problem of bomb design and assembly is treated separately in Chapter 12, which gives a glimpse of the work of the special laboratory set up at Los Alamos precisely for this purpose. A short final chapter (13) summarizes the whole account—and ends with a call for an acute social consciousness to grapple with the weighty issues which the successful prosecution of the project has raised (Section 6, "Planning for the Future"; Sections 7 and 8, "The Questions before the People"). Lastly, Appendixes 3, 4 and 5 are included for the benefit of the semi-professional nuclear physicist. They give, as examples of the type of fundamental research work carried out in the course of the development programme, brief accounts of an investigation of the delayed neutrons of fission and of the construction and testing of the first self-sustaining chain-reacting pile (which was brought into operation on December 2, 1942, at an initial energy output of 0·5 watt)—also a representative list of eighteen titles taken from the index of reports written by the Chicago workers during 1942.

It will be evident from this brief digest of the contents of the Smyth Report that it cannot fail to make interesting reading. To the general reader the earlier chapters may appeal more than the later ones; the account of the administrative handling of this vast project will certainly be a revelation to the industrialist—it is without question the history of the most complex and extensive industrial project ever brought into co-ordinated operation within a period of little more than two years; it is also, by implication, the story how, in a country of free institutions, under the stress of total war, many hundreds of millions of dollars were expended and many thousands of persons were employed without Congressional sanction or knowledge ("Because of the restrictions of military security there has been no chance for the Congress or the people to debate such questions").

* Statements relating to the Atomic Bomb. (London: H.M. Stationery Office, 1945.) 4d. net.

To the scientist, however, the later chapters will probably have the greater appeal. Unless he has been associated with the project he will scarcely have heard of the 'transuranic' elements 93 (neptunium) and 94 (plutonium). To him, Chapters 7 and 8 will be particularly illuminating. He will be able to read for the first time a connected account of an altogether amazing achievement in transmutation. A chemical species which does not occur naturally on the earth, and for which the astrophysicist has never produced evidence of occurrence in the stars, has been manufactured on an industrial scale: kilograms—probably hundredweights—of uranium have been transformed, atom by atom, into something strange and new, and, as a by-product, energy has been released at a power which, if expressed in thousands of kilowatts, must certainly involve numbers which are large. He will be interested, too, to know something of the methods by which isotope separation has been achieved for the heaviest of the terrestrial elements—how many kilograms of the rare isotope uranium 235 (natural abundance 0·7 per cent!) have been separated, practically pure, by a bold development of the electromagnetic method, which before the War had been made to yield merely a few micrograms of the separated isotopes of lithium and boron for particular experiments (Chapter 11).

No one can possibly detract from the achievement of the scientists and engineers who brought this amazing project to success in the United States within days which were numbered; but a British reviewer may be pardoned for returning to the subject of the contribution which his colleagues belonging to this country made in the earlier (as to some extent, also, in the later) phases of the work. Let it be said, then, that the Smyth Report recognizes the reality of this contribution. It records the fact that a suggestion was made through the British scientific liaison office in Washington, late in December 1940, that plutonium 239 appeared worthy of serious consideration as material for a bomb (Chapter 3, Section 17), also that the definitive report of the Committee of the National Academy of Sciences dated November 6, 1941, was more conservative than the British report of July 15, 1941 (progressive action being taken on the former only in view of its reinforcement by the latter report; and because of "general urging by a number of physicists"—including Urey and Pegram, who had just returned from a visit to Britain: Chapter 3, Sections 21 and 23). It states quite clearly "The British, particularly J. Chadwick, were convinced that a U235 chain reaction could be achieved. . . . They feared that if the Germans got atomic bombs before the Allies did, the war might be over in a few weeks. The sense of urgency which Pegram and Urey brought back with them was of great importance" (Chapter 4, Section 47). More could scarcely be expected by way of acknowledgment from an ally and partner (if the reader wishes to learn more of the British effort he should consult the White Paper referred to above). In view of this, it is doubly unfortunate that a charge should be levelled against the "foremost nuclear physicist" of another ally, amounting, at the least, to an accusation of political unwisdom and irresponsibility. It would not appear that the section of the report in question (Chapter 3, Section 2) is factually correct, let alone temperate in utterance. This, however, is but one blemish in a generally admirable and objective presentation.

N. FEATHER.

PENICILLIN IN THE TREATMENT OF SYPHILIS

By DR. JAMES MARSHALL

IT is generally agreed that probability of cure in syphilis can only be assumed if, during five years after treatment, there have appeared no signs, clinical or pathological, of relapse or progression. Penicillin was first used in the treatment of syphilis as recently as 1943, and it is now known that the doses originally used were inadequate. We cannot, therefore, begin to estimate the value of penicillin as an agent for the permanent cure of syphilis.

It is possible, however, to describe the remarkable effects of penicillin on the lesions of syphilis at all stages and to give some indication of the short-term therapeutic results. Only the passage of time and careful observation of large numbers of cases treated by various methods will permit the place of penicillin in the treatment of syphilis finally to be evaluated.

Penicillin already bids fair to oust the arsenicals from their position as chief agents in the treatment of syphilis. It has one enormous advantage over arsenic, bismuth and mercury, in that it can be administered in any dosage without fear of dangerous toxic effects. (It must, however, be used cautiously in certain cases of late visceral syphilis for fear of therapeutic shock.) The immediate surface sterilizing action of penicillin in early contagious syphilis is profound and will doubtless have great repercussions in disease control in the future. One can predict that this advantage will, for a time at least, be offset by the fact that penicillin is already showing signs of producing a state of foolhardiness in those treated with it. Some patients with venereal diseases are already treating their conditions in the most light-hearted manner and repeatedly re-expose themselves to infection as soon as they think themselves cured. If penicillin were indeed a 100 per cent cure such people would harm only themselves; but, unfortunately, this is not the case.

Early Syphilis

The results of past experience allow certain generalizations to be made. It is not possible to cure human or animal syphilis by a single injection of penicillin no matter how high the dosage. Repeated injections are necessary. Intramuscular administration appears to give better results than the intravenous method, whether by multiple injections or by continuous infusion. Injections of penicillin in aqueous solution must be given every three to six hours. Penicillin does not penetrate into the cerebrospinal fluid; in spite of this, it is unnecessary to administer penicillin by the intrathecal route in neurosyphilis.

The original experiments on cases of early syphilis in the United States involved the giving of varying quantities of penicillin (60,000–1,200,000 units) divided into sixty doses injected intramuscularly every three hours for seven and a half days. Quite independent of the dosage, the immediate results were the same in all series. *Sp. Pallida* disappeared from surface lesions in an average time of twelve hours; lesions healed rapidly; and there was a rapid trend towards reversal of positive serological reactions.

Appraisal of results in patients treated with penicillin by these methods depends on the eventual appearance of evidence of relapse, clinical or serological, after some months. The indications are, however, that in the above dosage range, the lower the dosage the higher the relapse-rate. J. E. Moore[1] states that the indicated eventual early relapse-rate with a total dose of 60,000 units in seven and a half days is 100 per cent; with 300,000 units about 75 per cent; with 600,000 units about 40 per cent; and with 1,200,000 units about 15–20 per cent.

Variation of the time factor has also been studied. When doses between 600,000 and 2,400,000 units were given in thirty injections in four days, the results were not so good as when the same doses were given in sixty injections over seven and a half days. The results of further increasing the total time of administration are not yet known. It has been established that spacing injections at intervals of twelve hours is not satisfactory, but it is not known whether three- or six-hour intervals make any material difference.

These early results suggested that increased dosage of penicillin was likely to produce a further fall in the relapse-rate, and at present the standard dose of penicillin for early syphilis is 2,400,000 units given in sixty injections over seven and a half days. Experimental series are being treated with even larger doses. Very good results have been obtained in the United States in two small series of cases treated with penicillin (60,000 and 300,000 units) and 'Mapharsen' (320 mgm.) over eight days.

My own experience with penicillin in early syphilis in men, using a dose of 2,400,000 units, confirms the general impressions of other observers. *Sp. Pallida* disappeared from surface lesions, in my cases, in an average of nine hours, and serial observations showed an increase in motility of the organisms just before their disappearance or death. Surface lesions healed as rapidly as in cases treated with arsenic and bismuth. Positive serological reactions reversed to negative in about the same time as in cases treated with arsenic and bismuth by rapid methods. A transitory increase in positivity of serological tests or a rise into positivity was sometimes seen during treatment when serial blood tests were made. The results of sixty-seven cases followed for at least six months are shown below:

EARLY SYPHILIS TREATED WITH 2,400,000 UNITS PENICILLIN

Primary sero-negative = 17 (of which 2 relapsed)
" sero-positive = 38 (of which 4 relapsed)
Secondary = 12 (of which 4 relapsed)
Total = 67 (of which 10 relapsed)
Average time for positive serological tests to become negative = 1·9 months
Analysis of relapse cases: cutaneous = 5; muco-cutaneous = 2, serological relapse = 1; sero-resistance = 2.

The incidence of relapse in this series was so high that, as will be described, the method of treatment was altered. Later observations and information have shown that failure after treatment of early syphilis with 2·4 million units of penicillin alone occurs in 7–8 per cent or more of cases followed u for six months or longer.

Relapse after Penicillin Treatment

Failure of penicillin treatment of early syphilis usually manifested by (*a*) cutaneous, muco-cutaneous or mucous relapse; or (*b*) serological relapse; o (*c*) sero-resistance; but a few rarer phenomena hav been described.

(*a*) *Surface Relapse.* In most cases the surface lesion heal rapidly under treatment. Occasionally, howeve cases are seen in which the chancre fails to heal completely and later breaks down again. Oftener th chancre heals completely but reappears on th original site after a latent period and may be accompanied by other surface manifestations of syphili Sometimes relapse phenomena are entirely 'secondary in type, the primary lesion remaining healed. Ev dence of serological relapse often, but not alway precedes or accompanies surface relapse.

Relapse lesions are often small and discrete an may entirely escape the notice of the patient. The ano-genital area should always be closely inspecte at the routine follow-up examinations, as it is common site for relapse phenomena of the condylomatous type. The interval between the end of treatment and the appearance of surface relapse ha varied, in my experience, between 59 and 200 days with an average of 83 days.

(*b*) *Serological Relapse.* In successfully treate cases of early syphilis, positive serum tests revers to negative in two to five months. Serological relaps is diagnosed when serial quantitative serum test show an increasing titre of positivity following phase of negativity or of declining positivity.

(*c*) *Sero-resistance.* Sero-resistance is diagnose at the end of an arbitrary period of six months cases where serial tests have shown a maintaine level of positivity. In some cases no decline in positivity follows treatment; in others there is a declin to a lower level, which is maintained.

Among the rarer relapse phenomena can be mentioned neuro-recurrence[2], ocular and osseous relapse and the persistence of *Sp. Pallida* in surface lesion at the end of the treatment period.

The criteria used in the past in the differentiation between relapse and reinfection with syphilis will n doubt have to be revised, but in the consideration of difficult cases it is well to recall the advice o Dr. Harry Eagle[3]: "in the evaluation of a new therapeutic procedure any treated case in which dark-field positive lesions develop within one to two years must be adjudged a treatment failure unless the evidence for re-infection is overwhelming".

Combined Treatment with Arsenic and Penicillin

The results obtained in early syphilis with a treatment lasting only seven and a half days are quite remarkable, but even with doses of 2·4 million units an important percentage of early infectious relapses still occurs. This relapse-rate is higher, in my experience, than with the 'twenty-day treatment' with arsenoxide and bismuth.

With the view of evolving a treatment which would reduce the relapse-rate, I consulted Dr. F. R. Selbie, who has been engaged in parallel experiments with rabbit syphilis[4]. He was of the opinion that using only penicillin, a really high cure-rate might be attainable only at dosage-levels of 10 million units and more, and that the best line of experimenta proach in the circumstances was by combining senical and penicillin treatment.

As a speedy complete treatment was an essential r my patients, it was decided to combine a modified rm of intensive arsenotherapy with penicillin at e previous dosage level. In order to give an adeuate amount of arsenic and yet avoid so far as possible e toxic phenomena always associated with rapid rsenotherapy, the treatment evolved consisted in the dministration of 0·09 gm. 'Neohalarsine' (arsphenxide tartrate) or 0·06 gm. 'Mapharsen' on two days ut of every three to a total of fourteen injections twenty days. (Previous experience had shown this ethod of distribution of injections to be almost ncomplicated by toxic reactions.) The total amount f arsenoxide (840 mgm. 'Mapharsen' or 1,260 mgm. Neohalarsine') approximates to two thirds of the mount usually given in the 'twenty-day' arsenoxide reatment, and is the smallest quantity of arsenic, hich, given by a rapid method, might be expected lone to cure a reasonable percentage of cases of arly syphilis.

The results in seventy cases so treated and followed or at least six months are shown below.

ARLY SYPHILIS TREATED WITH 2,400,000 UNITS PENICILLIN AND ARSENOXIDE

rimary sero-negative	17		
rimary sero-positive	30	Relapse	0
econdary	16		
elapse sero-negative	2	Cases failing to show tendency to reversal of positive serological tests—0.	
elapse sero-positive	5		
Total	70		

Average time for positive serological tests to become negative = 1·5 months

In a later series of patients, in order to reduce the ime spent in hospital, the plan was changed and he arsenoxide part of the treatment was given in en daily injections, each of 0·06 gm. 'Mapharsen' or 0·09 gm. 'Neohalarsine'. The incidence of minor oxic arsenical reactions was increased slightly by he closer approximation of the arsenical injections, but no major toxic effects have so far been encountered.

More than two hundred cases have now been treated by one or other of these methods of combined therapy, and the results, so far, appear better than with penicillin (2·4 million units) alone or with the 'twenty-day arsenoxide treatment'. Only three cases of relapse, all muco-cutaneous, have been seen or notified. It is of particular interest that two of the three patients who developed relapse phenomena had previously been treated for syphilis (one with 2·4 million units penicillin, the other with neoarsphenamine and bismuth) and the combined treatment was given as a result of failure of the original treatment.

Late Syphilis

The osseo-cutaneous lesions of late syphilis heal rapidly under penicillin treatment, and I have seen good clinical results in cases of gummata of the testicles. Interstitial keratitis in late congenital syphilis reacts equivocally.

My own relatively small experience with cases of late and latent syphilis with persistently positive serological reactions (in spite of arsenical and bismuth treatment) does not suggest that penicillin, in the dosage now employed, is very effective in producing reversal.

The results of treatment of visceral syphilis are difficult to assess. It may be noted, however, that the penicillin treatment of three cases of arterial syphilis (two of aortitis, one of aneurysm of the femoral artery) has been effected without evidence of therapeutic shock. Penicillin treatment was started without preparation with mercury or bismuth, the only precaution being that in the first forty-eight hours the individual doses were of only 10,000 units each.

In cases of late syphilis I have always used penicillin in a total dose of not less than 4 million units (for example, 100 injections of 40,000 units in aqueous solution). I consider it advisable to consolidate this treatment of attack with a long-term treatment with bismuth, or arsenic and bismuth, according to the type of case, over at least six months.

Neurosyphilis

Although penicillin does not penetrate into the cerebrospinal fluid in demonstrable quantities during the penicillin treatment of syphilis by the methods described, there is no doubt of its effect in neurosyphilis of all types.

Nelson and Duncan[5] report excellent clinical and pathological results in ten cases of early syphilitic meningitis treated with 600,000–4,000,000 units in seven and a half to eleven days. My own experience has been the same. One of my cases of secondary syphilis with meningitis is interesting in that the original abnormalities in the cerebrospinal fluid had disappeared two months after treatment with 2,400,000 units penicillin, and the fluid remained normal six months later when relapse became evident in a rising titre of positivity of serological tests and in the appearance of a general enlargement of lymph glands.

Stokes[6] reports that abnormal cerebrospinal fluids in late syphilis are improved by penicillin in 74 per cent of cases, and that improvement is marked in 33 per cent. The commonest change is a drop in the number of cells and in the quantity of protein. Symptomatic improvement of varying degrees can be achieved in general paresis, tabes dorsalis, meningovascular syphilis, recent ocular nerve palsies, optic papillitis and papillœdema. It remains to be seen whether such changes, clinical or pathological, will be maintained.

The optimum dosage in neuro-syphilis is as yet undetermined. Under investigation in America at present are: (1) repeated courses of relatively small doses, for example, 1,000,000 units at intervals; (2) single courses of 2,000,000–6,000,000 units within eight to twenty days; (3) malaria plus 2,000,000–4,000,000 units of penicillin simultaneously; (4) malaria followed by penicillin.

My own scheme of treatment in neurosyphilis now consists in the administration of 4,000,000 units penicillin followed by consolidatory treatment with an arsenical (trivalent or pentavalent according to the type of case) and bismuth for at least six months. Immediate results, clinical and pathological, have been good and improvement has been maintained in all cases. The speed with which gross abnormalities in the cerebrospinal fluid reverse to negative after penicillin treatment is often spectacular.

Congenital Syphilis: Prevention and Treatment

Lenz, Ingraham, Beerman and Stokes[7] have reported on the treatment of syphilis during pregnancy and infantile congenital syphilis with penicillin. Only a small number of cases was studied, but there are indications that penicillin has good effects on mother and child in syphilis during pregnancy. Miscarriage, stillbirth and neonatal death can be averted, and infants are born apparently healthy.

Infants with congenital syphilis were given 28,600–34,200 units penicillin per kilo body weight, distributed in fractions at four-hour intervals over eight days. The results as shown by clinical and serological response and by X-ray observation of the bones were very good.

Platou and associates[8] have treated sixty-nine cases of infantile congenital syphilis with doses of 16,000–32,000 units penicillin per kilo distributed over seven and a half days with good symptomatic results. Of thirty-nine cases followed from four to twelve months, twenty-five remained apparently cured, nine were still sero-positive but progressing towards negativity, and five had relapsed serologically (of which two relapsed clinically). They recommend treatment with 40,000 units per kilo.

The few pregnant women I have treated for early syphilis have been given 2·4 million units penicillin and a standard ten-week course of neoarsphenamine and bismuth. Only one of the series has as yet come to term and she was delivered of a healthy child.

Treatment Reactions

Local pain, sometimes quite severe, may be caused by certain batches of penicillin. This may be due to impurities, and it has been noted that in such cases the penicillin powder is often a dark orange or brown colour. The therapeutic efficiency is not impaired.

Cutaneous eruptions of erythematous or urticarial type are sometimes seen during treatment but do not necessitate interruption of therapy. Shock, with pallor, sweating and rapid pulse, early in the treatment is sometimes seen. A few such cases have occurred in our series, but treatment was never interrupted. Such reactions may possibly be due to impurities in the penicillin.

An important and almost constant feature in cases of early syphilis is a fever, sometimes high, which begins about twelve hours after the first injection and lasts for twelve to twenty-four hours. This is probably a variety of Jarisch–Herxheimer reaction, as a transitory increase in cutaneous eruptions or œdema around the chancre often occurs at the same time. In the few cases of late syphilis we have treated, this febrile reaction has not been noted. American observers have, however, noted the occurrence of therapeutic shock (for example, transverse myelitis, convulsions) in patients with late syphilis of the nervous system, and advise a cautious start with reduced doses of penicillin in such cases.

Lloyd Jones[9] reports venous thrombosis as a complication in a series of cases treated with penicillin intravenously in large doses (up to 500,000 units).

Summary and Conclusions

Penicillin is an effective agent in the treatment of syphilis at all stages. The early results with the dosage schemes already used are encouraging, but final judgment must be deferred until a significant number of cases has been followed for a period of at least five years. There is some reason to believe that the relapse-rate in early syphilis is inversely proportional to the dosage of penicillin, so that a better cure-rate may be attained when larger doses are employed.

The use of aqueous solutions of penicillin necessitates the hospitalization of patients with syphilis. Until this difficulty is overcome, it must, for various reaso reduce very considerably the number of patients w can have the treatment. Progress in the study of effects of retarding media (for example, beesw peanut oil mixture) suggests that a method m soon be available for adequately treating syphilis w one or two injections of penicillin each day.

It appears that penicillin and the arsenicals ha a synergistic action when used simultaneously. Pen ing the results of large-scale controlled experimen and as a means of conserving penicillin, I wou advocate for routine use in early syphilis so method of combined therapy. For patients requiri a rapid complete treatment (for example, mercha seamen) the arsenoxide-penicillin treatment scribed above is suggested; for those who c attend as out-patients, a week's hospitalization 2·4 million units penicillin, during which time can begun a standard ten-week course of injections neoarsphenamine and bismuth.

Every case of late syphilis deserves individu assessment; but as a basic principle, I consider th penicillin should always be followed by a long-ter treatment of consolidation with a suitable arsenic and bismuth.

In conclusion, I must point out that my prese advocacy of combined therapy in the treatment syphilis does not imply that penicillin alone is i capable of producing a cure. The optimum treatme for syphilis is still undiscovered. Penicillin in larg doses or by different methods of administration m provide the answer. In the meantime, the combin tion of penicillin with other anti-syphilitic remedi deserves further investigation.

OBITUARIES

Prof. J. T. Wilson, F.R.S.

James Thomas Wilson, emeritus professor o anatomy in the University of Cambridge, died o September 2 at the age of eighty-four years.

An Edinburgh graduate and a pupil of Sir Willia Turner, Wilson went to Australia as a demonstrato of anatomy in the University of Sydney when he wa twenty-six years old; three years later, independen chairs of anatomy and physiology were created an Wilson was elected as the first holder of the Challi professorship of anatomy. This position he held fo the next thirty years, during which time he built u a fine department, a tradition for thoroughness i scientific investigation, and a great reputation as university administrator of sound judgment and wit an unusual breadth of vision. He was dean of th Faculty of Medicine, and, among many interests and responsibilities outside the University, he served with distinction in the Australian Intelligence Corps, being promoted honorary colonel in 1915.

During this period, Wilson collaborated with Sir arles Martin and, more particularly, with Prof. P. Hill in research work, as a result of which many pers of fundamental importance were published on e structure and development of monotremes and arsupials. The late Sir Grafton Elliot Smith was e of his earliest pupils, and there is no doubt that ilson's guidance and stimulating influence must ave counted for much in laying the foundations for s later brilliant work.

In 1920, Wilson accepted the chair of anatomy at ambridge. Although a comparative stranger, his utstanding abilities were quickly recognized, and he ined the respect and affection of all who worked ith him in the University, and of the society of St. ohn's College, where he was elected to a fellowship the same year. His work for the Cambridge natomy School is well known. During his fourteen ears tenure of office, he enlarged and reorganized e course in anatomy for Part I of the Natural ciences Tripos, created an excellent departmental brary to which he gave a great part of his private ollection of books and papers, and attracted each ear a small number of students to take anatomy in art II of the Tripos.

Wilson's scientific work was always characterized y meticulous care and thoroughness, and his papers ere models in their exactness of expression and ucidity. The value of his contributions to natural cience was recognized by his election into the fellowhip of the Royal Society in 1909. In his later years, while at Cambridge, he spent a considerable part of is time in perfecting a technique by means of which series of sections of large embryos could be exploited o the greatest advantage; the enthusiasm which he howed in the development of the method, and in the lemonstration of his specimens to those immediately round him, was wholly characteristic; it is a great oss to embryology that but few of the many critical nd original observations which he made as a result were published.

After his resignation from the chair at Cambridge n 1934, he continued to lead a full and active life; that his judgment was held in the highest esteem to the end is evidenced by the fact that this year, at the age of eighty-four, he was asked to continue his Carnegie Reports for a further year. He was the first overseas member of the Anatomical Society of Great Britain and Ireland, and he acted as its president during the years 1922–24.

This record of scientific and administrative achievement alone would place Wilson high in the ranks of great medical teachers, but his greatness and influence were more profound and far-reaching than can be indicated by a mere statement of facts. His personal example and his friendship had a marked and lasting effect on generations of students; medical men who were trained at Sydney during Wilson's time still say, when his name is mentioned, "Oh, you mean Jummy", and go on to speak of him with a spontaneous fervour delightful to hear. He had great charm of manner and a natural power of inspiring those around him; he was actuated by the highest ideals, the sincerity of which was recognized and appreciated by the members of his staff and by his students. As with his scientific work, thoroughness and enthusiasm permeated every aspect of his teaching; he gave without stint of his time, knowledge and experience, and no one could fail to be the better man for having met and worked with him.

H. L. H. H. GREEN.

Prof. W. H. Fraenkel

THE death occurred on July 14, 1945, of Prof. Walter Fraenkel, who was living at Perth Amboy in the United States. He had been expelled from Germany early in 1939 by the Hitler Government and, after spending nearly a year at the University of Cambridge, as guest of the Metallurgical Laboratories, emigrated with his family to the United States.

Fraenkel's work covered problems of the age hardening of aluminium alloys, diffusion, segregation and crystallization and chemical reaction between metal and slag; the latter in close co-operation with R. Lorentz. Fraenkel held a professorship in Frankfurt-am-Main and there most of his research work was done, with the help of a small band of enthusiastic and devoted pupils.

Two short periods in industrial research during the First World War and in the thirties gave him an opportunity of learning about industrial problems and the industrial way of technical development.

Prof. Fraenkel was a physical chemist (trained under Bredig and Lorentz) and his approach to problems of metallurgy was always from this angle, as was the method of his teacher in this field, Tammann. He even introduced the kinetics of reaction into metallurgy in his work on the age hardening of duralumin, a problem which fascinated him during almost the whole of his research work. His studies on this subject were among the earliest scientific work done on this important theme.

I happened to be the first student who chose a subject in Prof. Fraenkel's own line of research for a thesis. The work was carried on in closest collaboration with him. He knew and watched every step and, in long and almost daily discussions, an intimate view of the man and his work was obtained, and also no small inspiration from his general attitude towards science and scientific work. His rigorous criticism of any results, be it his own or other workers, without regard to name and reputation, his modesty and his complete devotion to the cause of truth and science, were among his outstanding characteristics.

In spite of the almost pessimistic severity of his general outlook and many personal disappointments, Prof. Fraenkel possessed a keen sense of humour and a caustic wit that spared nobody, least of all himself. All his pupils and his colleagues will honour his memory as that of a man of high principles, a most capable and careful man of science and teacher and a kind and reliable friend.

E. SCHEUER.

Dr. William Cramer

WILLIAM CRAMER was born in the Rhineland on June 2, 1878. After taking his Ph.D. at the University of Berlin in 1901, he worked in its department of pharmacology. There he met E. F. Bashford, and their friendship resulted in his joining the staff of the Imperial Cancer Research Fund in 1903. Thus he came to collaborate with Bashford and Murray in that pioneer work which contributed so much to our knowledge of the growth of cancer under experimental conditions.

In 1905, Cramer went to Edinburgh as lecturer in chemical physiology in Sharpey-Schafer's Department, and took the degree of D.Sc. three years later. He published "Directions for a Practical Course in Chemical Physiology" in 1912, which ran to four editions. His position as a university teacher became somewhat difficult on the outbreak of the First

World War, and through the good offices of Dr. J. A. Murray, then director of the Imperial Cancer Research Fund, he rejoined its staff. Back in London, he completed his medical studies at University College Hospital and took the diplomas of M.R.C.S., L.R.C.P. in 1917. His intellectual versatility and wide scientific interests found expression in the numerous papers he published between 1915 and 1939, which embraced almost every aspect of the cancer problem. Never slow himself to enter the realm of scientific speculation, he protested only last year against a tendency in cancer research "to exalt theories over facts, to make facts fit into the Procrustean bed of a theory". He was specially interested in the hormonal factor in cancer, and a by-product of his investigations in this field was the book he published in 1928, entitled "Fever, Heat Regulation, Climate and the Thyroid-Adrenal Apparatus". He retired from the Imperial Cancer Research Fund at midsummer 1939.

After taking part in the Seventh International Genetical Congress in Edinburgh in August 1939, Cramer journeyed to America for the Third International Cancer Congress. Afterwards he joined t research group which Prof. E. V. Cowdry of St. Lou University organized at the Barnard Skin and Canc Hospital for a special investigation into epiderm carcinogenesis. He became chief pathologist to t Hospital, and in 1941 delivered the Middleton Gol smith Lecture to the New York Pathological Societ

Cramer died in Denver, Colorado, in August la a victim of the disease to the study of which he h so assiduously devoted the greater part of his li

R. J. LUDFORD.

WE regret to announce the following deaths:

Sir Edward Farquhar Buzzard, K.C.V.O., emerit regius professor of medicine, University of Oxford, December 17, aged seventy-three.

Dr. E. W. Kemmerer, the well-known internatio economist, formerly professor of economics a finance in Princeton University, on December 16, ag seventy.

NEWS and VIEWS

Royal Institution: Appointment of Prof. E. K. Rideal, F.R.S.

As recently announced, Prof. E. K. Rideal relinquishes his post as professor of colloid science in the University of Cambridge to succeed Sir Henry Dale as Fullerian professor of chemistry in the Royal Institution and director of the Davy Faraday Research Laboratory. Prof. Rideal's great breadth of scientific interests and achievements, so befitting his new position, must have received considerable stimulus from an unusually varied career. A scholar of Trinity Hall, Cambridge, he graduated there in 1911. Upon the outbreak of the First World War he joined the Royal Engineers and was later invalided from France to the Munitions Inventions Department. During 1919–20 he was visiting professor of physical chemistry at the University of Illinois, and afterwards returned to Cambridge as Humphrey Owen Jones lecturer in the Department of Physical Chemistry.

In 1930 Rideal was elected a fellow of the Royal Society; and the University of Cambridge, assisted by a grant from the International Education Board, set up a Department of Colloidal Physics with Rideal as its first professor. Shortly after, the Plummer bequest enabled the original temporary professorship to be consolidated, and the Department became the Department of Colloid Science, its objects being the study of the physics and chemistry of colloids and their application to biology. Under his guidance a small but enthusiastic nucleus concerned themselves chiefly with the study of insoluble monolayers and catalysis by solid surfaces, laying the basis for a reputation which was soon to become international. The Department grew steadily in numbers; by 1939 it housed some twenty-five research workers, the variety of nationalities represented being paralleled by the diversity of activities, which had by now spread quite naturally into the field of high polymers. To all, however complex the problem, Prof. Rideal's stimulating discussions and detailed personal interest were a never-failing source of inspiration.

War brought inevitable changes in its train. Langmuir troughs were set aside and more urgent problems taken up at the request of Government and Service Departments. This entailed innumerab committees and considerable travelling; but despi enforced absences, Prof. Rideal still gave his usu courses of lectures and showed an almost uncann acquaintance with the details of the by now incredibl mixture of activities housed in his Department. H inspiration and optimism, which never visibly faile are familiar to all who met him in those days. Th return of peace saw the Department's numbe standing at thirty-five, an acute problem of accom modation but a testimony to his war-time leadershi His many friends in Cambridge and elsewhere, an that widely spread body of his past pupils, will joi in expressing their great pleasure at his appointmen and will wish him every success in his new field o activity.

Chemical Engineering at the Imperial College: Prof. D. M. Newitt, F.R.S

PROF. D. M. NEWITT has been appointed to th Courtaulds chair of chemical engineering in th Department of Chemical Engineering and Applie Chemistry, Imperial College of Science and Technology, London. The recent munificent gift to th Imperial College by Courtaulds, Ltd., has mad possible the establishment of this chair; a trust ha been set up to administer the funds, which amount t about £118,000.

Prof. Newitt has been associated with the Department of Chemical Technology at the Colleg since 1920, where he studied under Prof. Bone an Dr. Hinchley, who was then in charge of the chemica engineering section of the Department. For man years Prof. Newitt acted as one of Prof. Bone's chie assistants in researches on combustion, being particularly associated with the work on explosions a high pressures. This led him to his well-know studies of the behaviour of materials at extrem pressures up to 20,000 atmospheres, for which skil and originality in engineering design and specia knowledge of the properties of highly stressed materials were required. In the development of industrial processes operating at high pressures he ha been able to give most valuable advice, and he ha ontributed to advances in the design of compressors nd of vessels to withstand high pressures. During he War, Prof. Newitt was in charge of the research work of the Inter-Services Research Bureau and was esponsible for many important developments. He s a member of the Heyworth Committee on the gas ndustry which has recently reported. He has also ecently had the opportunity of visiting schools of hemical engineering in the United States of America. Prof. Newitt combines experience of research work n a wide field of engineering and physical chemistry with teaching experience which augurs well for the School of Chemical Engineering at the Imperial College.

Card File of Physical Constants of Substances

THE general plan of the American "Annual Tables of Physical Constants", started in 1941 under the National Research Council, called for publication of tables on loose sheets, by sections according to properties, and also of a card file of numerical data of physical magnitudes, by substances. The card file represents a departure from the customary method of recording and filing data dispersed in the literature. They are to be assembled in the card file for each substance in a permanent predetermined order of physical properties, instead of being tabulated for each property, for a list of substances. Thus all physical properties for a given substance are brought together, adding up to a complete numerical description of the substance; and the non-availability of certain data for the given substance becomes immediately noticeable by the absence of the section number of the corresponding property on the substance chart. The actual numerical values are inserted whenever they are expressible by a figure or a few figures; extensive tables of data are not as a rule reproduced. It is expected that microfilm distribution facilities and reading devices will be available in the near future, so that one may obtain microfilm copies of any scientific publication desired. This will render extensive reproduction of voluminous tables superfluous and further justify the present scheme.

The cards are being planned as follows: Elements in the alphabetical order of their symbols, inorganic compounds in the alphabetical order of their formulæ, organic compounds also in the usual order of their overall formulæ by increasing numbers of the carbon and hydrogen atoms. However, as the data are on loose cards, users, if they choose, can re-order their card files by any other principle which they may prefer. As new numerical material is published, additional cards will be issued for substances already covered. Likewise revised cards will be supplied whenever necessary to replace old cards which may become obsolete. It is planned to issue about two thousand substance cards a year in instalments of a hundred cards. One drawback of the use of the small-sized card, 5 in. × 3 in., is that it may involve a large number of cards per substance; for example, bromine requires eighteen cards. The subscription price is based on the rate of 5 cents a card, that is, 100 dollars a year for a set of 2,000 cards. Auxiliary cards will be supplied at 1·5 cents a card or 5 dollars for the set, whichever is the less. Publication at practically nominal prices has been made possible by grants and subsidies provided mainly by industrial corporations and a generous donation from the Carnegie Institution. Correspondence should be addressed to "Annual Tables of Physical Constants", Frick Chemical Laboratory, Princeton, New Jersey.

The Association for Planning and Regional Reconstruction

IN response to many requests, the Association for Planning and Regional Reconstruction has decided to develop its Information Service, and subscribers are now to be offered, in addition to copies of all the Association's broadsheets and reports and the services of the library and the information bureau, a bi-monthly bulletin containing a report of work being undertaken by the Association as well as a résumé of matters of interest in the planning world and pre-publication news of books produced by the Association to ensure subscribers being able to obtain these when published. The first information bulletin, October–November 1945, continues as No. 160 the progress sheets issued since February 1941. The bulletin includes a selected list of recent acquisitions to the Association's library, and a revised edition of Broadsheet O, dated September 1945, giving general information about the Association and containing a complete list of broadsheets issued to date, has also been published. The Association, which aims at serving as a centre for research in the planning field and undertaking factual investigations, as well as acting in an advisory capacity and furthering the establishment of technical and other standards, and the development of new conceptions of planning, works closely with the School of Planning and Research for Regional Development, which is under a separate board of management. The School has enrolled more than a thousand correspondence students in the Armed Forces and among prisoners of war, and those who on demobilization reach a certain standard are eligible for a three months completion course, the successful students in which will be exempt from the final examination of the Town Planning Institute.

Training of Engineers

IN his presidential address before the Institution of Mechanical Engineers, delivered on October 19, Prof. Andrew Robertson emphasized that the training of engineers is concerned very much with "a knowledge of science and the technique which must go with it", to which must be added qualities of character. The needs of a healthily advancing industry show that mechanical engineering can usefully absorb a considerable increase (twice the pre-war number is suggested), in the output of universities and technical colleges, of young men trained to the standards of engineering degrees or of higher national certificates. "There is a definite field for the technical college distinct from that of the faculty of engineering," the range of activity of the former being from crafts at one end to higher national certificate and specialized technological work at the other. "The aim of a university department should be to produce potential leaders of the profession."

National certificate courses, successfully begun twenty-four years ago, should be further developed; part-time day release should be encouraged; opportunities for superior technical college students to attend full-time courses should be provided; the universities and industry should co-operate intimately in the production of scientifically trained men, not omitting college apprentices; engineering faculties should consider the advisability of instituting 'general honours' and 'special honours' degrees; the educational scheme of Britain should be so designed that at every stage promising students may be transferred to the course best suited to them; "there is a real need for an extension of post-graduate work both in research and in specialised studies in the fields of technology and administration, for established technical staff and executives"; some advanced students might with advantage work in the laboratories of the research associations. These and many other valuable suggestions are ably dealt with by Prof. Robertson in his discussion of engineering as a basis of a liberal education.

National Maps of Britain

A CIRCULAR from the Ministry of Town and Country Planning directs attention to a new series of maps of Great Britain constructed to illustrate various aspects of national life and resources. The scheme is a development of the idea of a National Atlas originally prepared by a committee of the British Association in 1939 and is now under the guidance of both the Ministry of Town and Country Planning and the Department of Health for Scotland. The maps are being published by the Ordnance Survey. All maps are to be on a scale of 1 : 625,000, or about ten miles to an inch, and all will bear the new national grid. Each map will be in two sheets, covering respectively (1) Scotland and the northern part of England and (2) the remainder of England and Wales. Those sheets already published are the base map, land utilization, administrative areas, topography, population density in 1931, types of farming and land classification. Several of these are new compilations. Shortly to be ready are sheets showing population of urban areas in 1938, roads, coal and iron resources, and iron and steel production. Others in hand include a physical map, with accepted terminology of physical features, grasslands of England and Wales, geology, electricity supply, gas, railways, population changes, various economic maps, and seaports. The price of the published sheets is generally five shillings.

Colorado Beetle in England during the War

THAT the freedom of the potato crop in England from the ravages of the Colorado beetle during the War was due not to good fortune but to the vigilance of the Ministry of Agriculture is evident from an article (*Agriculture*, 52, p. 210) describing the infestations that have occurred in various parts of the country in recent years. Since the outbreak at Tilbury in 1933 (which was only the second recorded in Great Britain) a close watch had been kept on potato crops, particularly in coastal areas. During 1936–39 a few beetles were reported in soils along the south-east coast and on ships in port, and, when military traffic across the Channel started, the precautionary measures were intensified. In 1941, however, beetles were discovered at six separate localities in the west of England, three of them being on inland farms in Devonshire. The special methods adopted for exterminating the pest were increased publicity and inspection, precautionary spraying of crops within a five-mile radius of an outbreak, and the restriction of potato growing to fields which had carried the same crop in the previous year. Approximately 30,000 acres of potatoes were inspected, beetles being discovered at five localities in the south-west counties in 1942. One further outbreak occurred in Wiltshire in the following year, and since then no infestations have been reported, though a few beetles were discovered on vessels and aeroplanes of cross-Channel services. The pest has evidently not yet established itself in Great Britain; but growers are asked to keep a constant watch and notify the Ministry at onc of any circumstances which arouse suspicion tha the beetle may be present. Unauthorized sprayin is strongly discouraged as it may cause the beetle to spread.

Use of Fertilizers in Britain

THE need for maximum food production in Grea Britain during the War called for the highest efficiency in the use of what fertilizers were available, and it i generally agreed that a drive for still further im provements must be made in the future if agricultur is to be put on a sound footing. In "Fertilizers Durin the War and After" (Pamphlet No. 13. Bath and West and Southern Counties Society. 2*s*.), Dr. E. M Crowther gives a comprehensive and most lucic survey of the subject, which will both be a valuabl guide to all concerned with crop production, and also of considerable historic interest. After comparing the pre-war consumption of fertilizers in Great Britain with that of neighbouring European countries and the United States, it describes the war-time rationing scheme for England and Wales, discusses the basis upon which it was founded and shows how the experience from large-scale field experiments has been utilized. It is impossible to give an adequate picture of the range of subjects dealt with, but among the newer aspects mention may be made of fertilizer placement. Results from field trials indicate that labour may be saved and the efficiency of fertilizers increased if small amounts of well-prepared fertilizer are placed in definite positions near the seed at the time of sowing. Another development that may well occur in the future is in the use of standardized compound fertilizers, which have proved so successful during the War. As regards the fertilizers themselves, Dr. Crowther considers that the technical efficiency of both making and using phosphate fertilizers needs to be improved, and he puts forward a plea for some revision of the Fertilisers and Feeding Stuffs Act Regulations, so that full advantage may be taken of current and future research.

The Tata Memorial Hospital

AMONG the buildings of Bombay the strikingly modern design of the Tata Memorial Hospital for the treatment of cancer and allied diseases must stand out with a distinctness which will direct attention to the beneficence of its purpose. Founded by the trustees of the late Sir Dorab Tata as a memorial to the philanthropy of Mr. J. N. Tata and his two sons, Sir Dorab and Sir Ratan, this fine hospital came into being in 1941 and has issued its first triennial report. Designed and built after consultation with experts from Manchester, London, New York, Cleveland, Paris, Stockholm and Brussels, the hospital is now staffed by Indian surgeons, anæsthetists, radiologists, pathologists and physicists, many of whom were sent abroad while the hospital was being planned and built, to gain special instruction and experience. The result is a hospital which can take its place beside any centre for the study and treatment of cancer, and it is not surprising that its superintendent, Colonel Sir J. N. Duggan, can report that it has, in spite of the handicaps of the war years, gained for itself a fine reputation. Any institution which can achieve, during a war like the one which has just ended, a standard of work like that which is here described, may congratulate itself. Future reports of its peace-time work will be awaited with interest.

Limitations of Science

In a paper "Methods of Research" (*J. Univ. Bombay*, **12**, March 1944, and **13**, March 1945), Prof. D. D. Kanga stresses the limitations of the scientific method in the modern world and the need for supplementing it, both in the world of affairs and in the sub-atomic world, by another training and discipline capable of transforming the present selfish, exploiting animal-man into a self-sacrificing, co-operating human being, willing to share with others. This technique Prof. Kanga terms the 'occult method', and emphasizing the importance of developing character, he believes that the chief drawback in our present system of education is the lopsided development of the individual. The university, he thinks, should address itself to this problem. In an earlier paper, "Knowledge Alone is not Enough to Solve our Problems" (*J. Univ. Bombay*, **12**, Part 3, November 1943), Prof. Kanga urged that it is the duty of a university to see that its curriculum provides for the development of its alumni equally from all sides; alongside science we require spiritual strength and spiritual qualities to enable us to resolve the many deadlocks confronting us in the world to-day.

Pitfalls in Prehistory

A short paper by Prof. C. van Riet Lowe of Johannesburg (*S. African J. Sci.*, **41**, 345; 1945) deserves to be noted by prehistorians elsewhere. It describes remarkable instances of artefacts transferred to surprisingly deep deposits by torrential river action; flaked pebbles from Carboniferous glacial gravels, betrayed by glacial striations; neolithic celts dispersed by a Norwegian settler in the last century; a soda-water bottle under 20 ft. of river-gravel; a wagon-wheel 23 ft. below a river bed, associated with a rolled palæolith; faked glass beads of German fabric, like those from Zimbabwe, reflecting a temporary fashion in amulets about 1908, and widely distributed in Transkei; a stone Chinese Buddha in undisturbed soil along the route of the Voortrekkers of 1837; and more Roman coins to add to those already known from various parts of South Africa and Rhodesia. The writer ends with an appeal to settlers, travellers, and field-workers not to discard any worked objects in situations where their presence may mislead.

Supernova in Canes

The June issue of *Sky and Telescope* contains a short reference to the discovery of a supernova in N.G.C. 5195, a satellite of the famous Whirlpool galaxy *M* 51. M. L. Humason was observing this satellite for the first time in three years, and on April 6 he noticed a faint star with which he was not previously familiar. The following evening he obtained its spectrum, which confirmed his suspicions that it was a supernova. At the time of discovery it had passed maximum by about 65 days. On April 12 the nova was at magnitude 16 photographic and 14 photovisual; its estimated maximum brightness was 11·0 photographic. It was fortunate that Humason had *M* 51 down on his observing programme on April 6, because the star was fading so rapidly that in a few weeks it would probably have been overlooked. A supernova appears in a spiral nebula on an average once in four hundred years, and this makes the coincidence all the more remarkable. In addition, the star would probably have escaped detection if it had not been so close to the central nucleus.

The Night Sky in January

New moon occurs on January 3d. 12h. 30m. U.T., and full moon on January 17d. 14h. 46m. The following conjunctions with the moon take place: Jan. 1d. 15h., Mercury 0·2° N.; Jan. 17d. 04h., Saturn 2° S.; Jan. 17d. 07h., Mars 2° N.; Jan. 24d. 11h., Jupiter 4° S. In addition to these conjunctions with the moon, Mars is in conjunction with Saturn on Jan. 22d. 17h., Mars being 4·4° N. Occultations of stars brighter than magnitude 6 are as follows: Jan. 12d. 17h. 39·1m., 147 *B* Aries (*D*); Jan. 14d. 01h. 57·8m., 85 H Tauri (*D*); Jan. 24d. 06h. 10·4m., 80 Virgo (*R*). The times are for Greenwich and (*D*) and (*R*) refer to disappearance and reappearance respectively. Mercury can be seen in the morning hours, rising at 6h. 25m. and 7h. 13m. at the beginning and middle of the month. Towards the end of the month the planet rises about the time of sunrise. Venus is too close to the sun during January for good observation, rising about 20 minutes before the sun on Jan. 1 and 15 minutes after the sun on Jan. 31. Mars, in the constellation of Cancer at the beginning of January, moving later into the constellation of Gemini, rises early in the evening and is well placed for observation throughout the night. The planet is in opposition with the sun on Jan. 14. Jupiter, in the constellation of Virgo, rises at 1h. 36m. on Jan. 1 and about midnight on Jan. 31. Saturn, in the constellation of Gemini, is visible throughout the night and does not set before the late morning hours. The earth makes its closest approach to the sun on Jan. 2. The Quadrantid meteor shower occurs during the first few nights of January.

Announcements

Prof. E. D. Hughes, professor of chemistry at the University College of North Wales, Bangor, will deliver the Tilden Lecture of the Chemical Society on January 17 at 5 p.m.

Mr. Paul G. 'Espinasse has been appointed lecturer and head of the Department of Zoology in the University College of Hull.

Standard Telephones and Cables, Ltd., have formed a central laboratory organization to undertake long-term research and development in the telecommunication, electronics and allied fields. The new laboratories, to be known as Standard Telecommunication Laboratories, Ltd., will be housed at Progress Way, Great Cambridge Road, Enfield, pending the erection of suitable permanent premises. They will have as their principal objective the intensification of research and development in all aspects of telephony, telegraphy, electronics, cables, radio, television, etc., and the various divisions of the Laboratories will be under the direction of specialists in the different spheres.

A Conference on "The Needs and Problems of the Family", arranged under the joint auspices of the British Social Hygiene Council and the Town and Country Planning Association, will be held at British Medical Association House, London, during January 24–25. Further information can be obtained from the Secretary, British Social Hygiene Council, Tavistock House North, Tavistock Square, London, W.C.1.

Erratum.—*Nature*, November 24, p. 626, col. 2, par. "British Bryological Society": *Dicranum strictum* is a recent addition to the flora of Surrey, not Britain as printed.

Determination of Factors Injurious to Plants in Acid Soils

Crop failures on acid soils are well known to farmers and to scientific workers interested in plant nutrition, and to both the remedy of liming is equally familiar. There exists, however, little knowledge concerning the relative importance of the various factors which produce the injurious effects observed on acid soils, and the subject is in need of intensive study. The evidence regarding the possible factors concerned are discussed by Russell[1], and it will suffice here to mention the main probable causes of injury: (1) direct injury of hydrogen ions; (2) lack of available calcium; (3) lack of available phosphorus; (4) excess of soluble aluminium; (5) excess of soluble manganese; (6) biotic factors (for example, mycorrhiza).

In examining crop failures, workers at Long Ashton have studied in particular the visual symptoms shown by plants in the field and in sand culture[2], and this technique has been applied during 1944 and 1945 to a detailed study of soil acidity effects on two plants the runner bean (*Phaseolus multiflorus*) and the cauliflower.

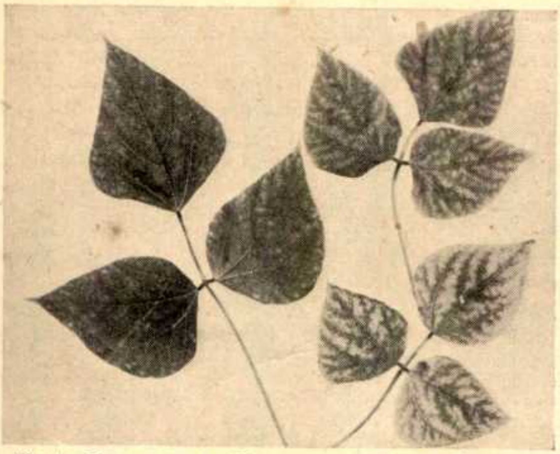

Fig. 1. Runner bean. High-manganese treatment. Comparison of manganese toxicity symptoms at high (left), medium (top right) and low (low right) calcium levels (June 18, 1945).

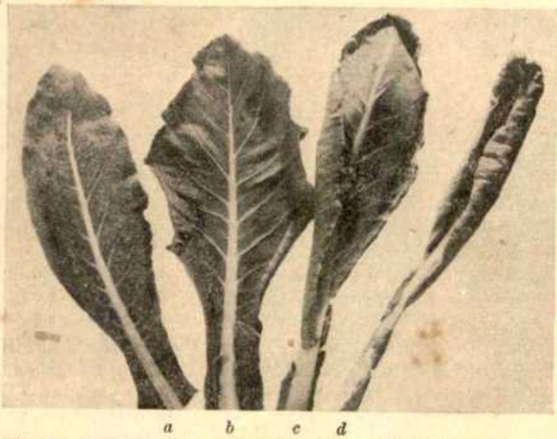

Fig. 2. Cauliflower. *a*, Calcium deficiency symptoms with low-(normal)-manganese. *b*, *c* and *d*, High-manganese treatment. Comparison of manganese toxicity symptoms at high (*b*), medium (*c*) and low (*d*) calcium levels. (July 6, 1945.)

In these investigations we have endeavoured to determine in sand cultures whether certain common and striking field symptoms are related to lack o calcium or to excess of aluminium or manganese, the *p*H being kept at a constant level throughout.

The results have shown that the characteristi 'field acidity' leaf symptoms of these crops, namely intervenal chlorosis and necrotic spotting of runne bean and incurled margins of cauliflower, are due to toxicity of manganese, though the toxicity effect are considerably modified by calcium status, being particularly severe when calcium is at a low leve and substantially decreased by a high calcium statu (Figs. 1 and 2). Using a plant-tissue test technique[3] as a measure of the solubility of manganese in the petioles, it has been shown that readily extractable manganese in the plant tissues is decrease by high calcium status.

The sand culture experiments were carried out according to a factorial design, using nutrient solutions with a constant *p*H of 5·2, with calcium, manganese and aluminium at the following levels. (Values are given as parts per million in the nutrient solutions.)

	Low (p.p.m.)	Medium (p.p.m.)	High (p.p.m.
Calcium	0	67	400
Manganese	0·3 (normal)	12·8	25·3
Aluminium	0·3 (normal)	5·5	11·0

As a basis to these experiments the true symptoms of calcium deficiency were determined in other cultures, where calcium was withheld and effects of manganese and aluminium were ruled out. In these it was established that the visual symptoms of calcium deficiency are as follows: *Runner bean*—leaves slightly pale green as for moderate deficiency of nitrogen, with necrotic spots, especially near tips and around margins, and progressing inwards intervenally. *Cauliflower*—young leaves distorted, with tips brown and sharply hooked either backward or forward; older leaves, marginal and intervenal areas become wilted and finally brown.

In the special experiments typical symptoms of calcium deficiency were developed in all the low-calcium cultures of runner bean, though in cauliflower the symptoms to date have only been slight, and no special leaf effects due to aluminium have so far developed.

In the medium and high-manganese series, however, the symptoms have been striking, the observations for the high-manganese series after five and seven weeks being summarized in Table 1.

Table 1. Severity of manganese toxicity symptoms.

Calcium level	Severity of manganese toxicity symptoms	
	23/5/43 (after 5 weeks)	7/6/45 (after 7 weeks)
Calcium *low*		
Bean	Moderate	Severe
Cauliflower	Trace	Severe
Calcium *medium*		
Bean	Slight	Moderate
Cauliflower	Nil	Slight—Moderate
Calcium *high*		
Bean	Trace	Slight
Cauliflower	Nil	Trace

Results of tissue tests made on June 7 and 15, after seven and eight weeks growth, are given in Table 2. They reflect clearly the increased amounts of extractable material of both elements according to the increased concentrations in the nutrient solution

TABLE 2. RESULTS OF TISSUE TESTS FOR CALCIUM AND MANGANESE IN PETIOLES.

Runner Bean (7/6/45).

Calcium level	Low			Medium			High		
Manganese level	Low (normal)	Medium	High	Low	Medium	High	Low	Medium	High
Element tested	Tissue test assessment								
Calcium	L+	L+	M−	M+	M+	M	H	H+	H
Manganese	Tr	H++	H++++	Tr	H+	H+++	Tr−	H−	H

Cauliflower (15/6/45).

Element tested	Tissue test assessment								
Calcium	L+	L	L	M+	M+	M+	H+	H+	H+
Manganese	Tr	H++	H++++	Tr	H++	H++++	Tr	H−	H+

H = High, M = Medium, L = Low; Tr = Trace.

and also the effect of high calcium status in lowering the amount of extractable manganese.

These results bring out clearly the importance of manganese toxicity in acid soils, a point also demonstrated for tobacco in Kentucky by Bortner[4], who showed further that the toxicity was decreased by phosphate treatments. They further emphasize the importance of the visual method as a means of diagnosis of the causes of crop failures due to defective nutrition, and of the sand culture technique as a means of analysing complex soil problems of plant nutrition.

The results of the investigations will be reported more fully at a later date.

The work has been carried out under special grants made by the Agricultural Research Council, to which grateful acknowledgment is made.

Measurement of the Diameters of the Living Eye by Means of X-Rays

SEVERAL of the pioneer workers in röntgenology—Rontgen included—recorded the fact that X-rays are perceived by the dark-adapted eye. Similar observations were made on radium rays, which were even held to surpass ordinary light as a source of illumination to the partially blind: radium rays were in fact used by one observer[1] for teaching at a blind school. Conflicting reports rapidly led to loss of all interest in the matter, until Taft[2] in 1932 clearly established the visibility of X-rays, and Pirie[3] simultaneously and independently directed attention to the possibility of 'reading with closed eyes' by means of X-ray light.

Possible applications to clinical ophthalmology were suggested by both these observers and by Gifford and Barth[4], and Newell and Borley[5]; while Rushton[6] in 1938 showed the axial length of the eye could be measured by throwing a beam of X-rays laterally on the posterior segment of the eye and moving this beam backward until its image became a point corresponding to the posterior apex of the globe. By noting the position of this point in relation to the image of the cornea reflected in a mirror, the axial length was obtained. Goldmann and Hagen[7] confirmed and extended this observation by recording the axial length of eighteen eyes.

The visibility of X-rays to the dark-adapted eye offers the opportunity of visualizing the shape and measuring all the diameters of the living eye. Such visualization and measurements can with advantage replace the 'schematic eye' (that is, a statistically computed average eye) in such practical problems as the localizing of intra-ocular foreign bodies and in the theoretical discussions on the nature and the varieties of the factors in the refraction of the eye.

Technique and findings. The subject undergoes fifteen minutes preliminary dark adaptation. He is then seated facing the X-ray apparatus in a darkened room with his head immobilized in a clamp. A slit beam of Rontgen rays, 0·5 mm. × 50 mm., is projected so that it traverses the eyeball with the plane of the beam at right angles to the diameter to be measured. This excites the sensation of vision where the beam transects the retina. By moving the beam from side to side without changing its direction with respect to the diameter and questioning the patient as to his visual sensations, it is possible to determine a position where the beam is tangential to the retina, that is, the position where the reported sensation is that of a point of light.

This position is marked by an exposure on a film introduced in front of the eye. The beam is then moved until it is again tangential at the opposite pole and its position again marked. On the developed film the distance between the two images gives the length of the diameter; thus any selected diameter can be measured provided its ends abut on the retina. As to the axial length, this is measured by determining the lateral projection of the posterior pole of the eye on a film by the method already described. A true lateral radiograph of the cornea is then taken on a dental film held at the inner canthus. A special cone is used carrying a cross-wire in its central ray, which impresses its image on both films. After development, the films are related to each other by superimposing the images of the cross-wire and the axial length measured between the corneal image and the slit image. With slight variations this technique can be employed in the localization of foreign bodies.

Dosage estimations show that, during the examination, no part of the skin receives more than 15 r.

and no part of the eye more than 7 r.—values well within safe limits.

The average anatomically determined measurements of the transverse, vertical and antero-posterior diameters of the eye are: 24·1, 23·5 and 24·2 mm. respectively[8]. There are, however, considerable individual variations. This is, broadly speaking, confirmed by the following X-ray measurements in five eyes:

Case No.	Measurements of diameters in millimetres Transverse	Vertical	Antero-posterior
1	23	22	23
2	23	21·5	26
3	24	23	25
4	22	21	22
5	24	23·5	24

In one case we had the opportunity of checking the X-ray measurements when the globe was excised for a malignant tumour. The X-ray measurements were 13 mm., 14 mm., and 22·75 mm. in the transverse, vertical and antero-posterior diameters respectively. In the excised eye the length of the antero-posterior diameter was identical with that obtained by X-ray measurement; low readings for the transverse and vertical diameters were found to correspond to the diameters formed by the inner and lower walls of the bisected eye with the apex of the tumour, which was situated in the upper and outer quadrant of the globe.

We are indebted to Dr. J. W. McLaren for advice and interest, and to Dr. G. Spiegler for the measurement of X-ray dosage.

An Induced Carcinoma in the Fowl

HOWEVER applied, or wherever injected, blastogenic agents, including tar and carcinogenic hydrocarbons, viruses and radium, usually induce in fowls mesoblastic tumours, that is, sarcomata or leukæmias. So far as we are aware, the only exception to this statement are the carcinomata which Japanese workers claimed to have obtained by injecting Scarlet Red and related azo compounds into fowls[1,2,3,4].

It is of some interest therefore that we have obtained a carcinoma of the kidney in a cock with another nitrogen-containing carcinogen, 2-acetyl aminofluorene. War-time conditions have prevented a repetition of the experiment on a larger scale.

Five one-month old Rhode Island Red cocks received 2-acetyl aminofluorene in the food for forty-five weeks; the daily dose commenced at 3 mgm. and was gradually increased to 30 mgm. at the end of the experiment (total 5·5 gm.). Three animals died during the first year but no tumours were found. The two survivors appeared healthy for about eighty weeks, when they began to lose weight. They were killed when they were moribund in the eighty-seventh week of the experiment, forty-one to forty-two weeks after the drug was withdrawn. In one of them the cause of death was a rather atypical leukæmia. T liver was grossly enlarged, weighing 367 gm. (quart of the total weight of the bird) and almost the ent liver tissue was replaced by immature blood cel The myelopoietic process affected the spleen (5·5 gm in much less degree, and the peripheral blood co tained relatively few immature leucocytes. It w impossible to decide whether the leukæmic proce was due to a virus or to the action of 2-acetyl amin fluorene, as the incidence of spontaneous leukæm in fowls is rather high.

In the other bird, however, the findings from th etiological point of view were less ambiguous. Bot kidneys were enlarged, especially the right (18 gm. and converted into irregular masses. The surfac were covered with whitish-yellow nodules togeth with several cysts, and on cutting the rather toug organs the nodules were found to replace the great part of the kidney tissue. Histologically, thes nodules were seen to be composed of polyhedr epithelial cells which were invading normal kidne tissue. The tumour bore no resemblance to the sc called embryomal nephroma and had all the char acteristics of an anaplastic carcinoma. Since suc a carcinoma is not known to arise spontaneously i the fowl, it seems justifiable to attribute its develop ment to the action of 2-acetyl aminofluorene.

Our thanks are due to Drs. W. E. Gye and E Vazquez Lopez for their opinion on the tumou morphology.

A Fatal Case of D.D.T. Poisoning in a Child

THE following is an account of what is possibly the first recorded human death from D.D.T. poisoning.

On August 22, 1945, an African child aged one year seven months and weighing 10 kgm. found a bottle of 5 per cent D.D.T. in kerosene, and drank (about) 1 oz. of the mixture. Within ten minutes he began to cough and vomit, whereupon he was given palm oil by the neighbours. His general condition became progressively worse, and after one and a half hours the child became comatose, and had convulsions which, so far as can be ascertained, consisted of generalized fine tremors. He was later seen by an Army medical officer, who gives the following account: "Child was comatose, collapsed with no perceptible pulse, froth at the mouth. Atropine, grs. 1/400 was given and the stomach washed out, the stomach washings proving to be a yellow pultaceous mass of paw-paw (native fruit). No smell of kerosene was detected. Artificial respiration was given but the child died at 15.00 hours", that is, four hours after ingestion of D.D.T.

Post-mortem performed two hours after death showed pulmonary œdema as the only demonstrable macroscopic lesion. The main histological findings ore a cloudy swelling of the liver and of the kidneys and a marked œdema of the lungs.

Full details of this case will be published elsewhere*.

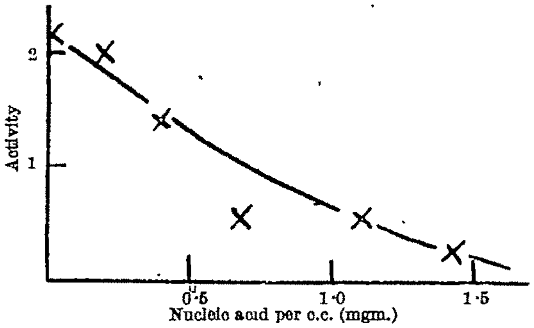
Adsorption of Enzymes on Solid Nucleic Acid

IN the course of experiments on an improved method for isolating and purifying the amylases of malt, I have found that solid yeast nucleic acid is a very powerful adsorbent of these enzymes. The figure shows an experiment in which varying quantities of the solid nucleic acid (B.D.H.) were added to diluted malt extract containing 0·12 mgm. nitrogen per mil, most of which is protein. The solution was gently shaken for a few minutes and then filtered. It can be seen that 1 mgm. of nucleic acid per ml. of solution removes the greater part of the enzymic activity. The enzyme can be recovered from the residue by the simple expedient of dissolving it in a few mils of dilute phosphate buffer of *p*H 6. For example, the following figures were obtained by the addition of 10 mgm. of nucleic acid to a malt solution containing 0·24 mgm. nitrogen per mil.

Activity in original solution	2 2
Activity in filtrate	0·6
Activity recovered from nucleic acid ..	1·5
Activity in wash water	0 2

The presence of nucleic acid in the solution appears to have no effect on the enzymic activity.

The malt extract used in these experiments contains both α- and β-amylases, but predominantly the latter. The activity was determined by adding 1 c.c. of the solution to 10 c.c. of 1 per cent soluble starch in a *M*/10 phosphate buffer of *p*H 6, for 10 (or 20) minutes at 37°, when the amount of maltose formed is determined by the method of Willstätter *et al.*[1]. This method determines primarily the β-amylase; but observations of the colour of the products with iodine indicates that the nucleic acid does not differentiate between the α- and β-amylases.



Compound formation between proteins and nucleic acid has been demonstrated in the past[2] by mixing solutions of protein and of nucleic acid and precipitating the complex with acid, and nucleic acid has been used in this way to precipitate enzyme as a step in purification[3]. I have not found any record of the observation of the reversible adsorption of enzymes on the solid acid. In view of the probable importance of nucleic acid in the processes of gene reduplication and protein synthesis[4], this phenomenon appears to be of considerable interest and is being further investigated.

I am much indebted to Mr. Adam Tait, of Messrs. Wm. Younger and Co., Ltd., for the gift of the malt.

Inhibition of the Development of *Fusarium oxysporum cubense* by a Growth Substance produced by Meredith's Actinomycetes

IN a discussion which we had early this year with Dr. Portheim of Kew Gardens, the latter raised the question of the use of antibiotics in the control of plant diseases caused by bacteria and fungi, and suggested that preliminary work which he had carried out supported his contention that gliotoxin-producing fungi might be found useful in combating such diseases. Dr. Portheim's views would appear to have been in part substantiated by the recent observation of Brian and McGowan[1].

At the suggestion of Dr. Portheim, we undertook to determine the gliotoxin production of a culture of *Trichoderma viridans*, supplied by him, when grown on the waste water used in the cleaning of beer casks, a medium claimed by him to be suitable for the cultivation of this fungus. As test organism for gliotoxin production a standard strain of *Bac. subtilis* was used which, on trial, had been proved to be inhibited in its growth by gliotoxin, supplied by Dr. Portheim, in concentrations of 6 parts per million.

Though the culture of *Trichoderma viridans* used grows abundantly on the beer wash water at temperature between 25° and 30° C., at no time did the growth liquid have an inhibitory action on the development of *Bac. subtilis*; and it was concluded that, under the conditions employed, the *Trichoderma* culture had failed to produce gliotoxin.

When these experiments were in progress, we became acquainted with Meredith's[2] observation that certain Jamaican soils are inhibitory to the spread of Panama disease, caused by *Fusarium oxysporum cubense*, and that certain Actinomycetes inhabit such soils. On isolation and subsequent cultivation of these Actinomycetes in extracts from their own soils, some of these organisms were found by Meredith to inhibit or retard the development of *Fusarium oxysporum cubense*.

Though Meredith does not ascribe the function of his antagonistic Actinomycetes to growth-inhibiting substances produced by them, we felt it worth while to explore to what extent this might be the case, and in this way possibly to bring further evidence in support of Dr. Portheim's contention that certain plant diseases can be controlled by antibiotics. For this purpose we secured cultures of Meredith's Actinomycetes from the National Type Culture Collection and grew them on Portheim's beer wash medium and on the waste liquors resulting from food yeast manufacture.

In both these media the Actinomycetes grew well; in the latter particularly when the liquor was diluted with equal parts of water.

After incubation at 30° C. for one month, the inoculated waste liquor from food yeast manufacture was covered by a pink pellicle of Actinomycetes. When 4 ml. of this medium, freed from living cells by centrifuging, was added to 10 ml. of wort agar, the mixture allowed no growth of *Fusarium oxysporum cubense*, even when the plate was heavily inoculated with a fresh culture of the fungus. Wort agar plates which had had 3 ml. and 2 ml. of the centrifuged Actinomycetes growth-liquor incorporated allowed restricted growth of the fungus. Control plates made up of wort agar with 4 ml. of the original medium, on which the Actinomycetes was to grow, showed abundant growth of the *Fusarium* within two days.

After five weeks growth in food yeast waste liquor, the concentration of the inhibitory substance produced by Meredith's organism had increased to such an extent that 1 ml. of the liquor sufficed to prevent growth of *Fusarium oxysporum cubense*.

Having established the toxic action of Meredith's organisms, preliminary attempts were made to isolate the active substance. These attempts, so far, have shown that the substance is thermolabile and that it fails to pass through a porcelain filter.

Further investigations on its action, its isolation, and its nature are in progress.

Insecticidal Properties of *Euphorbia* Extracts

IN the June number of the *Tropical Diseases Bulletin* (p. 502) there is a review of a paper by Mülhens[1] on the insecticidal properties of *Euphorbia dendroides* in Crete. I thought it might be desirable to place on record some tests on the insecticidal properties of *Euphorbia tirucalli* Linn. which were carried out during 1943 and 1944 in Tanganyika.

This, with other species of African *Euphorbia*, have been used for centuries as a fish poison; it is a common shrub throughout the whole of East Africa. The natives mash the green shoots with water and throw this into the pond or river; the fish float paralysed on the surface after a few minutes. It was thought that extracts might provide a cheap insecticide especially against mosquito larvæ.

Aqueous extracts of the fresh material had no effect on mosquito larvæ, but seemed to possess some insecticidal effect on adult Diptera. Extracts were then prepared by steeping 50 gm. of young shoots that had been dried in an oven at 100° C. in 100 c.c. kerosene for 48 hours. These extracts gave 100 per cent kill of adult *Glossina* and other Diptera, compared with 20–30 per cent kill given by the untreated kerosene. This recipe was sent to the Industrial Research Board, Nairobi, for further testing; however, it was reported that extracts made there had no appreciable insecticidal properties. The original extracts were then retested at Shinyanga with the same results as recorded above; but when further extracts were prepared from sun-dried shoots of *E. tirucalli*, no appreciable insecticidal properti were found. Owing to pressure of other work th investigation was stopped.

I mentioned these experiments to Mr. Culwic district commissioner, Mahenge, who stated that t African tribes in his district used *Euphorbia calycin* N.E.Br., the common candelabra euphorbia Africa, as an insecticide and claimed that it was ver successful. Further investigation also revealed the Africans used fresh branches of *E. tirucalli* to protec young plants from the ravages of grasshopper slugs, snails and other insects. I witnessed a tes carried out by Mrs. Fairbairn using young shoots *E. tirucalli* laid around various young vegetabl plants. Some plants were left untreated to serv as controls, and these were all devoured, wherea the *Euphorbia* afforded 100 per cent protection fo the others.

I suggest that this subject would be worth furthe investigation.

Aerial Bactericides

IN an earlier letter[1] we discussed the bactericidal action of lactic acid, mandelic acid and triethanolamine against airborne organisms freshly sprayed from the respiratory tract. Since then we have investigated the aerial disinfectant action of the homologous series of aliphatic α-hydroxy carboxylic acids RR_1C.OH.COOH, including glycollic acid, lactic acid, α-hydroxy valeric acid, α-hydroxy *n*-hexoic acid, α-hydroxy *n*-octoic acid, α-hydroxy *n*-decoic acid, α-hydroxy isobutyric acid, α-hydroxy-α-methyl butyric acid, cyclopentanol-1-carboxylic acid, and cyclohexanol-1-carboxylic acid. We have also investigated the aerial disinfectant action of the mono esters of maleic acid ROOC.CH=CH.COOH, including the methyl, ethyl, allyl, butyl and hexyl esters, and two mono esters of succinic acid, the ethyl and hexyl.

All the compounds which are listed above were effective in destroying the organisms of sprayed saliva (*S. salivarius* and others) and could be of use as aerial disinfectants. Some useful degree of activity may well be expected of other substituted glycollic acids. The effectiveness, as judged by the rate of destruction of bacteria-carrying particles, from a simulated sneeze, reached a maximum for the straight-chain series (R_1=H) at lactic acid. α-Hydroxy *iso*-butyric was the most effective of the disubstituted glycollic acids, being similar to lactic acid in this respect.

The most effective maleic acid ester was the ethyl ester, the maximum killing rate of which was again similar to that of lactic acid. The succinic acid esters appeared less effective than the corresponding maleic acid esters.

Unlike lactic acid and the earlier members of the straight-chain series, the disubstituted acids and the maleic acid esters can be volatilized, without appreciable decomposition, by simple heating. Also the rate of vaporization from relatively large surfaces at room temperatures is sufficient to maintain a useful bactericidal concentration.

Tests of these substances were carried out in an 800 cu. ft. room at temperatures between 60° and 75° F. and over a relative humidity range of 60–75 per cent. The bacteria were sampled on to serum agar plates in a slit sampler[3]. Further details of the actericidal action of these substances nder varying conditions will be published later.

Unit Cell and Space-Group of Co_2Al_9

In an investigation of cobalt-aluminium alloys by X-ray methods, Bradley and Seager[1] identified a phase Co_2Al_9 or Co_3Al_{13}, thus confirming the findings f earlier workers. The composition of the phase appeared to be invariable, but it could not be fixed exactly in the absence of knowledge of the structure. A phase $FeNiAl_9$ (or $FeNi_2Al_{18}$), found in the ternary system of iron, nickel and aluminium, is isomorphous with the cobalt-aluminium phase, and in a paper on aluminium-rich alloys of the ternary system, Bradley and Taylor[2] suggest that this phase is monoclinic. The work described below was carried out in order o test this suggestion.

An alloy containing 32·7 per cent cobalt and 67·3 per cent aluminium was made up in a high-frequency induction furnace under a low pressure of hydrogen. The alloy was annealed *in vacuo* at 900° C. for 48 hours and allowed to cool in the furnace, after which it was found to be brittle and could be easily crushed. Powder photographs were taken, but it was not found possible to interpret these satisfactorily on the basis of a structure with higher symmetry than monoclinic. Interpretation on the basis of a monoclinic unit cell, that is with four unknown quantities, is not practicable. It was therefore decided to try to isolate single crystals of the phase, so that the unit cell could be obtained directly from oscillation and Weissenberg X-ray photographs.

An examination of the crushed fragments under a microscope showed a small percentage of regularly shaped pieces. Some of these were mounted with shellac on glass fibres and photographed in an X-ray camera of 2·8 cm. diameter specially designed to reduce exposure time in these preliminary experiments[3]. The photographs so taken usually contained an irregular distribution of spots, showing that the fragment consisted of a number of crystals, but sometimes traces of layer lines could be detected. From the orientation of these layer lines the crystal could be set with one axis parallel to the axis of oscillation. When this was achieved it was often found that other crystals were also present, giving spots lying between the layer lines. Finally one fragment was found which gave layer lines with no spots between them; this was then known to be a single crystal.

From the single crystal obtained in this manner, the unit cell was found to be monoclinic with $a = 6{\cdot}18 \pm 0{\cdot}02$ kX., $b = 6{\cdot}24 \pm 0{\cdot}02$ kX., $c = 8{\cdot}59 \pm 0{\cdot}02$ kX., $\beta = 95° \pm 0{\cdot}5°$. With these parameters it was possible to index the lines on the powder photograph, thus showing that the fragment selected was of the same phase as the bulk of the material. From the unit cell dimensions combined with density measurements it is found that there are four cobalt and eighteen aluminium atoms per unit cell; the density calculated on this basis is 3·62 gm./c.c., which agrees with the observed density of 3·673 gm./c.c. Thus the composition is represented by the formula Co_2Al_9. The space-group is $P\,2_1/c$ which has four general equivalent positions per unit cell. Hence two of the aluminium atoms must lie on special positions on one of the four sets of centres of symmetry, but it is probable that all the other atoms are in general positions.

Further work on the complete determination of the structure is in progress.

A New Test for 2 × 2 Tables

May I reply briefly to some of Prof. R. A. Fisher's remarks[1] on my suggested test[2]?

First, Prof. E. B. Wilson[3] was concerned with tables in which all marginal totals were equal ($m = n = r = s$ in my notation). He calculated the distribution of the difference $(a - b)$ on the assumption that p was given by the column totals to be $\frac{1}{2}$; and his test was based on this distribution. Apart from the facts (a) that my proposal involves neither $m = n$ nor $r = s$, and (b) that my test is not based on the difference $(a - b)$, there is an essential difference of principle between my proposal and that of Prof. Wilson, in that he assumes p to be given by the column totals, while I make no such assumption. My validity condition explicitly covers all possible values of p.

Prof. Fisher's criticism[4] of Prof. Wilson was based primarily on this assumption about the unknown p, and it seems a valid criticism of this assumption; but my proposal is unaffected by it.

Secondly, I wish to emphasize that I do not believe that the conditions stated in my earlier letter for the validity of the test I proposed are *always* satisfied in practice. If they were, there would have been little point in stating them. Conditions can arise where it is altogether false to assume p constant. In such circumstances, we can only try to randomize beforehand; and then, if this is done, Prof. Fisher's test remains valid—a fact not always realized (for example, Wald[5]).

Thirdly, concerning Prof. Fisher's remark that the result where all animals die is irrelevant to the null hypothesis, it may be that this difference of opinion results from a difference of attitude. Suppose we consider two 'null hypotheses': (1) blue-eyed people are just as likely to catch colds as non-blue-eyed people; (2) taking a daily dose of *XYZ* does not affect the chance of having a cold. Each of these hypotheses might be tested by an experiment yielding a 2 × 2 table. But there is a difference of attitude. In case (1), we do not have in mind any proposal to do away with blue-eyed people in order to reduce colds; in case (2) we do have in mind giving people *XYZ*, if it should turn out to be good. In case (1) we *study* the world; in case (2) we propose to *change* it. Our conceptual universe in case (1) is a single fourfold one, in which a given individual can be classified by two distinct attributes—'blue-eyed' and 'cold'. In case (2) we have in mind two distinct two-fold worlds; one possible world, in which everybody has *XYZ* and each individual is classified according to the single attribute 'cold', and another world, in which people go without XYZ and again are classified by 'cold'. In case (2) we wish to decide which of these two possible worlds should be made the real one.

Now suppose all our experimental subjects catch colds. In case (1) we might say we learn nothing. But in case (2) we do learn—in fact it would seem not worth while to give people XYZ, since they seem to catch colds anyway. Of course, the evidence may not be conclusive; but such as it is, it is surely relevant.

Other points will, I hope, become clear in a forthcoming paper.

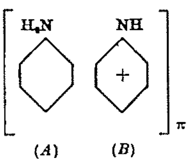
Mechanism of the Benzidine and Related Rearrangements

Two electronic theories have been proposed for the benzidine rearrangement[1,2], but both are open to criticism. The present theory is an elaboration of the Robinson[3] mechanism in terms of the quantum theory[4] of aromatic structure.

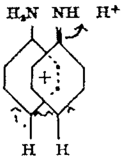
It is suggested that, in the initial hydrazobenzene salt (I), a non-localized π-electron migrates from ring 2 to ring 1 with consequent fission of the N–N bond to produce the complex molecule (II), composed of the aniline derivative A and the ion-radical B. Since the electron levels of the latter are incompletely filled, and since the π-orbitals of the rings will overlap, exchange forces should hold A and B together. The product will be called a π-complex. The 'π–π' bond in it will be of novel type, joining aromatic systems and not a pair of atoms, but it will be otherwise analogous to the bond in the helium molecule ion He_2^+. Rotation about the bond will be possible, but three positions of stability with intermediate energy-hills will be defined by the alternating polarities round the rings; in them the nitrogens will be opposite each other or 120° apart. The rings in the π-complex will be parallel and co-axial.

$\begin{array}{l}\mathrm{NH_2^+\ Ph\ (1)}\\ \mid\\ \mathrm{NH\ -Ph\ (2)}\end{array}$

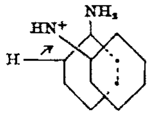
(I)



(II)



(X)



(Y)

If the p-substituents in the π-complex can be eliminated as positive ions, process X will be possible (dotted arrows indicate displacements of single electrons), leading to a benzidine. If reaction is delayed, rotation to a 120° position will allow the formation of a diphenyline by a type X process. Thirdly, process Y, involving a 60° or 180° orientation of the π-complex, will lead to a semidine; this involves a configuration corresponding to an energy-hill and should be less facile than X. If we assun that process X is in fact easier than Y only if involves a p-position of component A, all the dat on the benzidine rearrangement can be interprete in detail.

The products formed will depend not on th 'migratory aptitudes' of the groups but on the poi of attack of the proton catalyst; thus in Y the mo basic ring will function as component A and carr the free amino-group in the product. A diphenylin can form only if the more basic ring has a free *pa* position. These conclusions are confirmed in deta by the existing evidence. Moreover, in naphthalen derivatives, where rotation of the π-complex shoul be inhibited since the rings are not symmetrica diphenylines and p-semidines are in fact neve formed.

Similar π-complex intermediates can be writte for other analogous rearrangements (for exampl N-bromacetanilide, *para* Claisen, Hofmann, etc.)

The theory will be investigated and full details published elsewhere in due course.

Properties of Optically Isomeric Mepacrines

In a recent communication, Hammick and Chambers[1] report that whereas the racemic form of the well-known antimalarial drug mepacrine is given to human patients, only the lævo isomer of this drug is excreted in their urine. It seems appropriate to record here that the problem of biological relations of optically isomeric mepacrines has been dealt with in a number of Russian publications during the last few years. After the resolution of racemic mepacrine into its isomers by Chelintsev and Osetrova[2] in 1940, Gause and Alpatov[3] noticed that both isomers of this drug are equally effective against malaria, whereas the dextro isomer is about twice less toxic than the lævo form for mammals and birds. Further, Gause[4] recorded that the dextro isomer differs from the lævo form in the mechanism of its permeability into the living cell. Finally, extensive clinical studies made under the supervision of Prof. Tareev in the clinical department of this Institute confirmed the observations of Gause and Alpatov and showed that the pure dextro form of mepacrine is less toxic for human patients than the usual racemic form, but the strength of antimalarial action in both forms is the same. It is hence clear that the dextro isomer of mepacrine is very interesting from the therapeutic point of view.

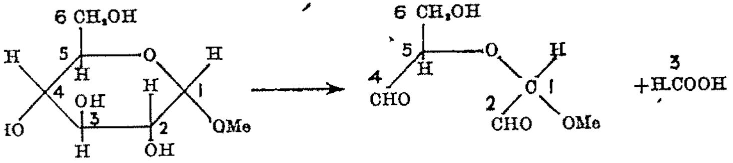
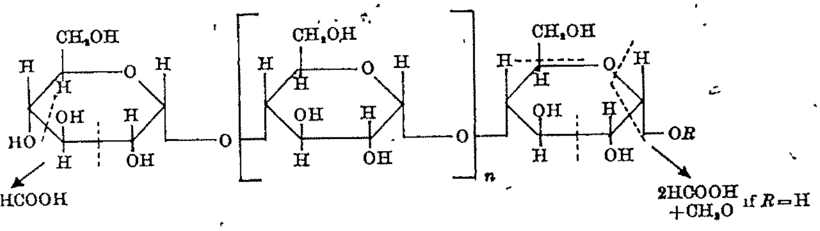
PPLICATION OF NEW METHODS F END-GROUP DETERMINATION TO STRUCTURAL PROBLEMS IN THE POLYSACCHARIDES

By F. BROWN, SONIA DUNSTAN, T. G. ALSALL, PROF. E. L. HIRST, F.R.S., and J. K. N. JONES

The University, Manchester

THE oxidative degradation of α-glycols by periodic acid has found many applications in carbohydrate emistry, one of the most important of these being . S. Hudson's[1] investigation of the reaction between is reagent and the methyl hexopyranosides, which e attacked with disruption of the ring and elimination of the third carbon atom of the hexose as formic cid. In the case of reducing disaccharides consisting f 1 : 4-linked hexopyranose residues, the reducing exose residue should yield a further 2 mol. of formic cid, giving three in all. The corresponding methyl iosides, on the other hand, contain the requisite ystem of contiguous hydroxyl groups only in the erminal residue, and should yield only 1 mol. of ormic acid. It follows that polysaccharides built up n the pattern of starch or cellulose with chains of : 4-linked hexopyranose residues should yield formic cid only from the reducing residues (if any) and from he terminal residues. If, therefore, the reaction ould be carried out quantitatively, an estimation of he formic acid produced would give a measure of he number of end-groups present.





n the other hand, polysaccharides containing : 6-linkages will give rise to 1 mol. of formic acid for every such monose residue which contains no ther substituent. If, therefore, end-group determinations by the periodic acid method and by the methylation method agree, evidence is provided that o 1 : 6-linked sugar residues containing three unsubstituted hydroxyl groups occur in the polysaccharide.

The marked tendency for oxidation of polysaccharides by periodic acid to proceed beyond the stage depicted above[2] has hitherto restricted the usefulness of the method, but the reagent has been used in other ways in the study of polysaccharides. For example, Barry and Dillon[3] showed that by use of periodic acid the stepwise degradation of the : 3-linked polysaccharide laminarin can be effected, and in the case of starch dextrins an attempt has been made to measure the formaldehyde produced from the reducing end of the chain[4].

Our interest in these reactions originated in attempts to gain further insight into the structure of plant gums, suitably bound side-chains of which we hoped to remove with the aid of periodic acid. We at once encountered difficulties due to over-oxidation, and a detailed study of the experimental conditions was undertaken. We have now found that suitable conditions for the quantitative liberation of formic acid from methyl hexopyranosides, methyl biosides of appropriate structure, cellulose, starch, glycogen and certain plant gums, are provided by the use of a solution of sodium periodate to which potassium chloride has been added. Potassium periodate is precipitated, but sufficient remains in solution to effect oxidation under conditions such that the formic acid is liberated quantitatively from the terminal sugar residues in about 180 hr. at 15° C. The concentration of reactants is important and the amount of starting material is so chosen that approximately 7 mgm. of formic acid are liberated per 100 c.c. of solution. The excess of potassium periodate is destroyed by addition of ethylene glycol, and the formic acid is then titrated by 0·01 *N* baryta. Alternatively, the formic acid can be extracted by ether and estimated by the mercuric chloride method or gasometrically from the amount of carbon monoxide produced by the action of sulphuric acid on the sodium salt. The utility and economy of the method are shown by the fact that an end-group determination can be completed in the starch series using as little as 0·5 gm. of material.

Experiments were carried out with the methyl pyranosides of xylose, arabinose, glucose, galactose, mannose, cellobiose and maltose, and also with sucrose, all of which give quantitatively 1 mol. of formic acid. A study was then made of the action of periodic acid on starch and amylopectin. In these materials the proportion of reducing end-groups is small in comparison with the proportion of non-reducing end-groups, and the observed values for the amounts of formic acid liberated can be used to calculate directly the proportion of non-reducing end-groups. It is to be noted, however, that for long straight-chain molecules such as amylose and cellulose, in which both reducing and non-reducing end-groups may be present, formic acid may be liberated from both the first and the last glucose residues, and the calculation must be adjusted accordingly. Nevertheless, for the mixtures of amylose and amylopectin which are present in starches the amount of formic acid given by the long-chain molecules of the amylose portion may be neglected, as a first approximation, in comparison with that given by the many non-reducing end-groups present in the branched chain molecules of amylopectin. The results (see table) have been expressed as the average number of glucose residues in the molecule for every end-group present (estimated experimental error ± 2 units).

In some instances independent end-group determinations were made by the standard methylation procedure. In these experiments the chromatographic method[5] was used for the quantitative separation of the tetramethyl glucose, and it was found to be easily possible to complete an end-group determination using less than 10 gm. of starch.

We then measured by potentiometric titration[6] (using a modification of the standard method kindly placed at our disposal by Mr. R. S. Higginbotham) the iodine-binding power of the various samples. The available evidence, which does not, however, cover the full range of starches, indicates that all amyloses possess similar iodine-binding powers[7], and on this assumption we proceeded to evaluate the amylose contents of the samples (column 2 of table). Since the amylose constituent contributes only negligibly to the formic acid liberated by the action of KIO_4 on starch, the figures in columns 2 and 3 of the table enable a calculation to be made of the chain-length of the repeating unit of the amylopectin portion of the starches. The results (column 5) show that for a wide range of starches the amylopectin component contains approximately twenty glucose residues per end group. Exceptions are the amylopectins of sweet potato (27) and arrowroot (25), but we prefer to postpone discussion of possible causes for these divergences until more is known concerning the iodine-binding power of the corresponding amyloses. Indeed, until further evidence is forthcoming, the possibility cannot be entirely ruled out that materials intermediate in structure between unbranched amylose and much branched amylopectin may yet be encountered. The rice starch examined differed from the previous sample in that for the whole starch there were 24–27 glucose residues per end group in contrast with the earlier figure of 30[8]. The possibility arises that the proportions of amylose and amylopectin may vary considerably for different samples, and this may be true for other starches also; for example, maize, in which widely different amylose contents have been recorded, and waxy maize, for which a higher figure (26) was previously observed[9] for the number of glucose residues per end group. Our present sample of waxy maize starch consisted entirely of amylopectin.

Substance	Amylose content %	Number of glucose residues per end-group		Calculated chain-length of repeating unit of amylopectin fraction
		By KIO_4 method	By methylation method	
Potato starch	18	28	25	23
Crude potato amylopectin	7	21		20
Sago starch	26	24		18
Banana starch	21	27	24	21
Sweet potato starch	18	32	30	27
Arrowroot starch	20	31		25
Tapioca starch	17	25		20
Pearl manioc starch	16	24		20
Rice starch	14	24	27	20
Maize starch	23	25		19
Waxy maize starch	0	20	20	20
Wheat starch	19	26		21

We have applied the method also to various samples of glycogen kindly supplied to us by Dr. D. J. Bell. For all these, the sources being respectively horse muscle, rabbit liver, human muscle, rabbit muscle (fasted), *Mytilus edulis* and *Ascaris lumbricoides*, our results indicated within the limits of experimental error a repeating unit of twelve glucose residues. The same figure was obtained by Bell[10] for horse muscle and rabbit liver glycogen, using the methylation method, and for *Mytilus edulis* glycogen by K. H. Meyer[11] (the others have not yet been examined by the methylation technique). The ne results considerably extend the list of glycogens whic have been found to contain a repeating unit of twelv glucose residues.

For cellulose, after making allowance for the formi acid produced at the reducing end of the chain, a valu of at least 1,000 residues per chain has been obtaine The range of application of the method is furthe shown by the results obtained with: (*a*) inulin[1] (repeating unit approximately 25 fructose residues calculated on the amount of formic acid liberated from the reducing end of the chain); (*b*) gum arabic (our results show that the repeating unit o mol. wt. 1220 found by Smith[13], using the methylatio technique, contains two end-groups which liberat formic acid, support being thus given to the molecula structure for gum arabic advanced by Smith); (*c* ε-galactan of larch wood (there are three end-group per repeating unit of mol. wt. 1104, in agreemen with our previous results[14] and with the formul suggested by White[15]; (*d*) pershore plum gum (th equivalent by acidimetry is 1,200 and the presen results show the presence of one end-group pe equivalent).

Preliminary experiments with other gums an pectic materials have been made and it is apparen from these that special problems arise when the polysaccharide contains terminal uronic acid residu Such substances readily undergo further oxidati with breakdown of the molecule and liberatio additional amounts of formic acid[16]. The pr reason for this behaviour is that after the oxidation is complete there are two >C=O g attached to the $-\overset{|}{\underset{|}{C}}-O-$ ring linkage of the original uronic acid residues. Similar conditions exist whe α-methylmannofuranoside is treated with potassium periodate, the sixth C-atom being removed as form aldehyde, leaving two aldehyde groups attached to the $-\overset{|}{\underset{|}{C}}-O-$ ring linkage. Here also further o tion readily takes place. We have found, fo ample, that zinc borneol glucuronoside and m α-methylgalacturonoside undergo oxidation wi formation of about four equivalents of acid, some of which is oxalic acid. Titrati do not remain constant but begin to fall a 200 hr. owing to the destruction of oxalic the experimental conditions employed.

MAMMARY CANCER IN MICE

N the introduction to this collection of essays*, Dr.
M. B. Shimkin sketches the historical development
our knowledge of mammary cancer in mice. Dr.
F. Bashford and his colleagues of the Imperial
ncer Research Fund were instrumental in estab-
hing the validity of using animal tumours in
perimental cancer research. Then Leo Loeb and
hers showed the important part played by hormones
mammary cancer. By developing and using inbred
ains of mice, American workers were able to in-
stigate the inheritance of mammary cancer and
veal the existence of extrachromosomal influence.
ie cytology, morphology and histogenesis of the
ammary gland and mammary tumours are dis-
ssed in four illustrated contributions. In general,
ly minor advances have been made in the mor-
ology of mammary tumours since the classical
ork carried out early in the present century. Dr.
. E. Heston reviews our knowledge of the genetics
mammary cancer in mice and describes the origins
d characters of the inbred strains of mice used in
ncer research. This work can be considered to have
mmenced in 1909, when Dr. C. C. Little started
eeding the *dba* strain, although some evidence that
e tendency to mammary cancer was inherited was
ilable before that time.

ie development of knowledge of the milk influence
he genesis of mammary tumours is reviewed by
L. B. Andervont. Early experiments showed
reciprocal matings between strains with high
v mammary tumour-rates, the mice born to
-cancer strain mothers develop cancer, while
iose born to low-cancer strain mothers remain
latively free of tumours. The extra-chromosomal
ctor influencing the incidence was shown by Dr.
J. Bittner, in a series of foster-nursing experiments,
be present in the milk of high-cancer strain mice.
he relative incidence of tumours and the latent
for the appearance of tumours in certain
s of mice vary with the dose of the milk factor,
ie response can be used for the biological assay
factor. The milk factor appears to be a nucleo-
n and is widely distributed in the tissues of
ncer strain mice. As the effect can be trans-
ugh mice without inducing tumours, the
like a latent virus infection. It differs
n viruses in its relatively long latent period.
riments with heterozygous mice showed
aary cancer was generally more common
than in virgin mice, and that the incidence
d by ovariectomy. The importance of
hormones in the incidence of mammary
ld only be clearly shown by treating male
gh-cancer strains which had both chromo-
extra-chromosomal factors for cancer.

tively uniform behaviour of mice from in-
s also makes it possible to study the effects
the incidence and growth of mammary
Dr. H. P. Morris describes many different
in which restriction of food intake or
ias reduced the incidence of cancer or
growth of existing tumours. In their
nstituents and biochemical processes,
tumours resemble other tumours more
an normal breast tissue. Dr. J. P. Greenstein points out that the end results of neoplastic growth are tissues which are chemically similar. The range of activity of several enzymes is much smaller among different tumours than among normal tissues. Mammary tumours in mice have been used extensively for experiments on chemotherapy of cancer, and Dr. Helen H. Dyer, in summarizing and tabulating the work in this field, concludes that no effective remedy has yet been found. Breast tumours in mice form the most valuable material available for such experiments. The probability that the cure for one type of cancer may not work on all types of tumour, however, makes it advisable that more than one type of tumour should be used in therapeutic experiments.

In the concluding essay, Dr. M. B. Shimkin considers the possible implications of the work on mice to human cancer. Whether mammary cancer in women is inherited is not yet known with certainty, so that we cannot say if a milk factor operates in humans or not. Even so, Dr. J. J. Bittner has suggested that it might be desirable to interrupt completely the nursing of daughters in whose family history carcinoma of the breast has occurred.

Mammary tumours in mice have been extensively studied, and the facts which have been obtained are well presented in this symposium. To what extent other tumours, or mammary tumours in other species, resemble these mouse tumours, particularly from the point of view of heredity, remain as interesting problems for the future.

STUDIES ON COMPREGNATED WOOD

EXPERIMENTS carried out at the Forest Research Institute, Dehra Dun, indicate that compregnated wood which compares favourably with foreign samples (tests on a foreign specimen of compregnated birch are given) can be produced from Indian timbers. In Indian Forest Leaflet No. 77—1945 (Utilization) entitled "Preliminary Studies on Improved Wood, Part III. Compregnated Wood" (published by Forest Research Institute, Dehra Dun, 1945), it is stated that wood of highly improved properties can be obtained by a suitable combination of impregnation, lamination and compression. In the case of compressed wood and lignostone, whole wood scantlings are used and, by application of great compression, the properties of the material are made uniform in the main direction. In the case of compregnated wood, the timber is sub-divided into veneers, and impregnated with resins, or thin films of glue are placed between the veneers; finally the pack is compressed at a high pressure at a suitable temperature. Alcoholic solutions of resin or film glues, such as Tego film, etc., are used. It is said that, by suitable choice of the species of wood, thickness of the veneers, pressure and temperature employed, and the direction of laying the veneers, the properties of the resulting material can be varied to meet particular requirements. The uses of this material, it is held, are very varied—aeroplane propeller blades are given as an example. The main defects of natural wood in this connexion are low hardness; low cleavage strength; low shear strength and great hygroscopicity. Compregnated wood, on the other hand, has high tensile strength; high shear strength to cope with the high centrifugal stresses at the boss, which at the same time are reduced to a minimum due to the low density of the material in contrast to metal; high damping capacity; favourable strength density ratio; lightness (weight of such blades are a third of metal ones); increases in efficiency (about 6 per cent) by the use of such blades; ease of repair; and finally, it is claimed, freedom from tiring, which is so frequently the cause of fatal air accidents in aeroplanes fitted with metal propellers. Other uses are gear wheels, bearings (ships' tail shafts, rolling mills, textile mills, etc.), fish plates, press forms, gun stocks, electrical machinery and so forth.

For the preparation of compregnated wood in the investigations, rotary cut, sawn or sliced veneers of different Indian timbers were used, some twenty-three species being experimented with. The adhesives employed were tar acid formaldehyde resins prepared in the laboratory, prolamin-formaldehyde dispersions, casein-formaldehyde dispersions or a suitable combination of these materials. The Leaflet, which is illustrated with photographs and tabular diagrammatic statements, discusses the methods and procedure employed in the investigation.

FORTHCOMING EVENTS

Saturday, December 29

Royal Institution (at 21 Albemarle Street, London, W 1), at 2.30 p.m.—Sir Robert Watson-Watt, F.R.S "Wireless" (Christmas Lectures adapted to a Juvenile Auditory, 2)

Tuesday, January 1

Royal Institution (at 21 Albemarle Street, London, W.1), at 2.30 p m.—Sir Robert Watson-Watt, F.R.S.: "Wireless" (Christmas Lectures adapted to a Juvenile Auditory, 3)

Television Society (at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W.C.2), at 6 p.m.—Mr. F. A. Inskip: "A Test Signal Generator for Television Receivers"; Mr. A. M. Spooner: "Cathode Ray Tube Quality Measuring Apparatus"

Wednesday, January 2

Royal Society of Arts (at John Adam Street, Adelphi, London, W C.2), at 2.30 p m.—Dr C. B Williams "The Migration of Butterflies" (Dr. Mann Juvenile Lectures, 1).

Thursday, January 3

Royal Institution (at 21 Albemarle Street, London, W.1), at 2.30 p.m.—Sir Robert Watson-Watt, F.R.S.: "Wireless" (Christmas Lectures adapted to a Juvenile Auditory, 4).

Royal College of Surgeons of England (at Lincoln's Inn Fields, London, W C.2), at 5 p.m.—Mr. N. L. Capener: "Physiological Rest—the Orthopædic Principle".

Association for Scientific Photography (in the Theatre of the British Council, 3 Hanover Street, London, W.1), at 6.15 p m.—Dr. A J. Holland: "Glass and Photography"

Friday, January 4

British Ecological Society (in the Washington Singer Laboratories, Prince of Wales Road, Exeter), at 10 a.m.—Annual General Meeting.

Institute of Physics, Electronics Group (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m—Prof. N Feather, F.R.S.: "Artificial Radioactivity".

Saturday, January 5

Royal Institution (at 21 Albemarle Street, London, W.1), at 2.30 p.m.—Sir Robert Watson-Watt, F.R.S. "Wireless" (Christmas Lectures adapted to a Juvenile Auditory, 5).

Monday, December 31—Saturday, January 5

Twenty-ninth Annual Conference of Educational Associations (at King's College, Strand, London, W.C.2).

Wednesday, January 2

At 5 p.m. (in the Great Hall).—Lady Simon: "The School, the Teacher and the Home" (Presidential Address).

Thursday, January 3

At 2.30 p.m. (in the Great Hall).—Discussion on "The Teacher's Profession" (to be opened by Mrs. M. D. Stocks and Mr. Nigel O. Parry).

APPOINTMENTS VACANT

Applications are invited for the following appointments on before the dates mentioned

Assistant Bursar—The Bursar, Queen's University, Belf (January 10).

Principal—The Clerk and Treasurer, Dundee Institute of Art a Technology, Bell Street, Dundee (January 12).

Patent Agent (qualified), preferably holding an Engineer Degree or equivalent qualification, by a large Engineering Compa electrical and mechanical—The Ministry of Labour and Natio Service, Appointments Department, Technical and Scientific Regist Room 572, York House, Kingsway, London, W.C.2, quoting F.5222 (January 12).

Deputy Borough Engineer and Surveyor—The Town Cle Town Hall, St. Marylebone, London, W.1, endorsed 'Deputy Borou Engineer and Surveyor' (January 12).

Lecturer in Hausa—The Director, School of Oriental and Afric Studies, University of London, London, W.C.1 (January 15).

Archæologist (man or woman)—The Keeper of the Museum Yorkshire Museum, York (January 31).

Professor of Chemistry—The Principal, Heriot-Watt Colle Edinburgh (April 22)

Professorship of Industrial Chemistry at Istanbul Univers —The British Council (Appointments Department), 3 Hanover Stre London, W 1

Bacteriologist to work on the intestinal flora, a Biochemi with good bacteriological knowledge for microbiological assay of t vitamins, and an Organic or Bio-Chemist for other work involvi vitamin assay—The Secretary, National Institute for Research Dairying, Shinfield, Reading.

Chemists (male), Inter. B.Sc. standard, as Assistant Works Chemi with large firm of cement manufacturers—The Ministry of Labour a National Service, London Appointments Office, 1–6 Tavistock Squa London, W C 1, quoting Ref. No. C.N.68
